scalecast-examples

Release 0.0.1

Michael Keith

Sep 20, 2023

NOTEBOOKS:

Welcome! Here we overview scalecast models and features. If you notice a typo, think something could be stated more clearly, or have any other suggestion or bug you want addressed, contact mikekeith52@gmail.com or open an issue.

Back to scalecast: https://scalecast.readthedocs.io/en/latest/

CHAPTER

ONE

INTRODUCTORY EXAMPLE

This demonstrates an example using scalecast `0.18.0`. Several features explored are not available in earlier versions, so if anything is not working, try upgrading:

```
pip install --upgrade scalecast
```

If things are still not working, you spot a typo, or you have some other suggestion to improve functionality or document readability, open an issue or email mikekeith52@gmail.com.

Link to dataset used in this example: https://www.kaggle.com/datasets/neuromusic/avocado-prices.

Latest official documentation.

[1]:
```
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
```

[2]:
```
# read in data
data = pd.read_csv('avocado.csv',parse_dates = ['Date'])
data = data.sort_values(['region','type','Date'])
```

1.1 Univariate Forecasting

1.1.1 Load the `Forecaster` Object

- This is an object that can store data, run forecasts, store results, and plot. It's a UI, procedure, and set of models all-in-one.
- Forecasts in scalecast are run with a dynamic recursive approach by default, as opposed to a direct or other approach.
- Forecaster Object Documentation.

[3]:
```
from scalecast.Forecaster import Forecaster
```

[4]:
```
volume = data.groupby('Date')['Total Volume'].sum()
```

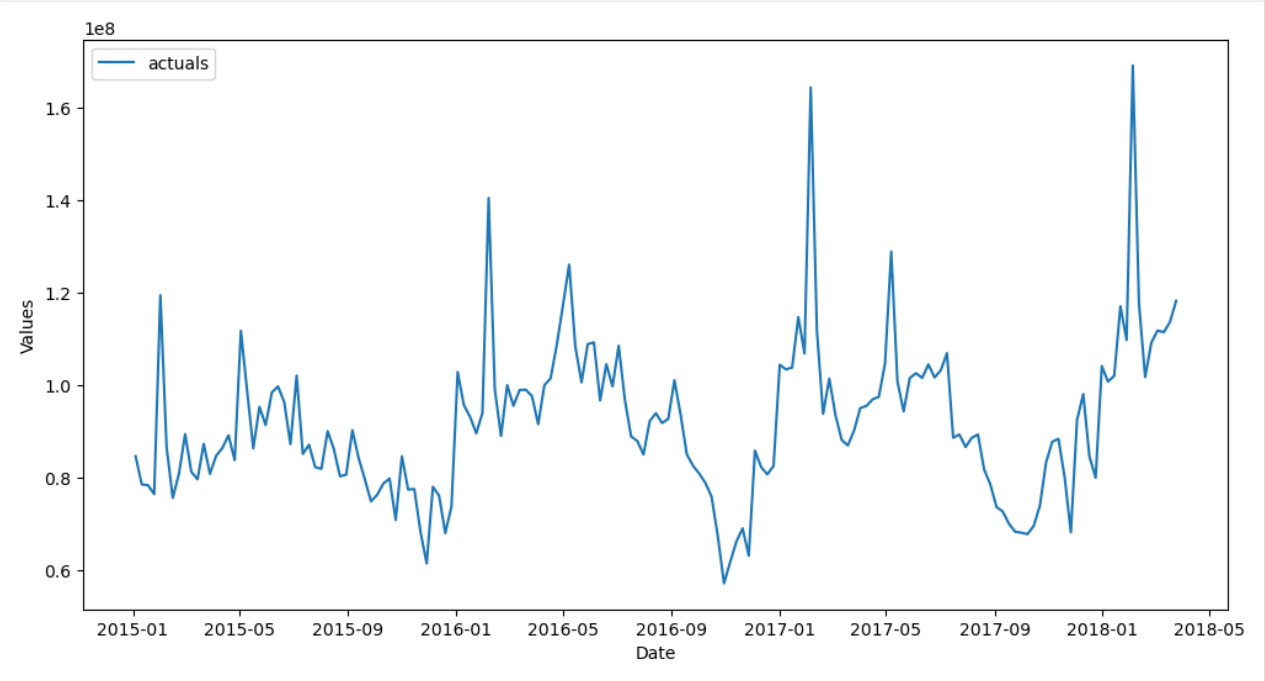
[5]:
```
f = Forecaster(
    y = volume,
    current_dates = volume.index,
    future_dates = 13,
)

f
```

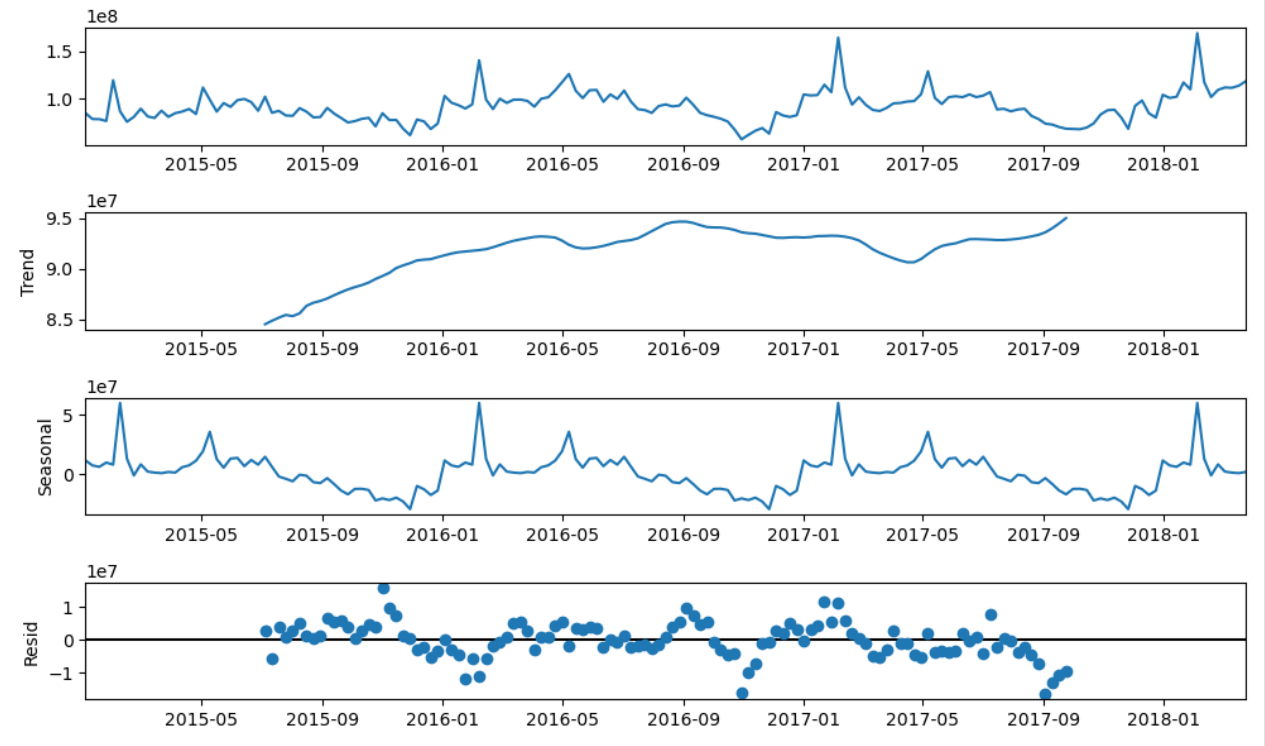
[5]:
```
Forecaster(
    DateStartActuals=2015-01-04T00:00:00.000000000
    DateEndActuals=2018-03-25T00:00:00.000000000
    Freq=W-SUN
    N_actuals=169
    ForecastLength=13
    Xvars=[]
    TestLength=0
    ValidationMetric=rmse
    ForecastsEvaluated=[]
    CILevel=None
    CurrentEstimator=mlr
    GridsFile=Grids
)
```

1.1.2 Exploratory Data Analysis

[6]:
```
f.plot()
plt.show()
```



[7]:
```
plt.rc("figure",figsize=(10,6))
f.seasonal_decompose().plot()
plt.show()
```

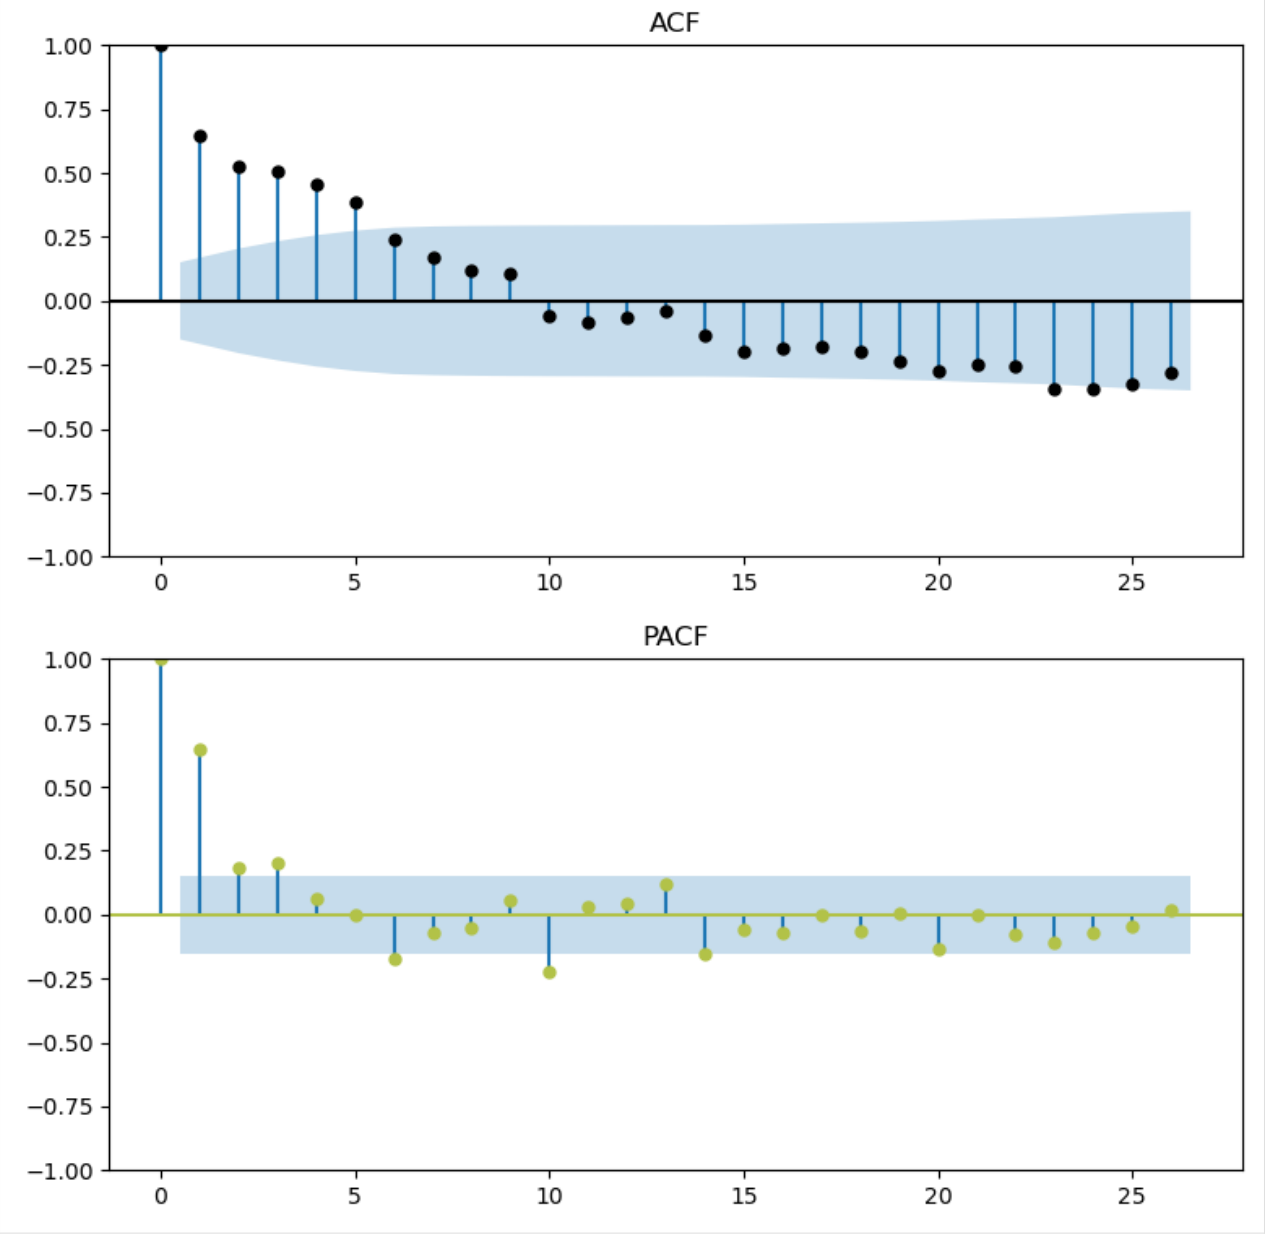


[8]:
```
figs, axs = plt.subplots(2, 1,figsize=(9,9))
f.plot_acf(ax=axs[0],title='ACF',lags=26,color='black')
```

(continues on next page)

(continued from previous page)

```
f.plot_pacf(ax=axs[1],title='PACF',lags=26,color='#B2C248',method='ywm')
plt.show()
```



1.1.3 Parameterize the `Forecaster` Object

1.1.3.1 Set Test Length

- Starting in scalecast version 0.16.0, you can skip model testing by setting a test length of 0.
- In this example, all models will be tested on the last 15% of the observed values in the dataset.

[9]:
```
f.set_test_length(.15)
```

1.1.3.2 Tell the Object to Evaluate Confidence Intervals

- This only works if there is a test set specified and it is of a sufficient size.
- See the documentation.
- See the example.

[10]:
```
# default args below
f.eval_cis(
    mode = True, # tell the object to evaluate intervals
    cilevel = .95, # 95% confidence level
)
```

1.1.3.3 Specify Model Inputs

Trend

[11]:
```
f.add_time_trend()
```

Seasonality

[12]:
```
f.add_seasonal_regressors('week',raw=False,sincos=True)
```

Autoregressive Terms / Series Lags

[13]:
```
f.add_ar_terms(13)
```

[14]:
```
f
```

[14]:
```
Forecaster(
    DateStartActuals=2015-01-04T00:00:00.000000000
    DateEndActuals=2018-03-25T00:00:00.000000000
    Freq=W-SUN
    N_actuals=169
    ForecastLength=13
    Xvars=['t', 'weeksin', 'weekcos', 'AR1', 'AR2', 'AR3', 'AR4', 'AR5', 'AR6', 'AR7',
↪'AR8', 'AR9', 'AR10', 'AR11', 'AR12', 'AR13']
```

(continues on next page)

(continued from previous page)

```
    TestLength=25
    ValidationMetric=rmse
    ForecastsEvaluated=[]
    CILevel=0.95
    CurrentEstimator=mlr
    GridsFile=Grids
)
```

1.1.4 Run Models

- See the available models.
- See the blog post.
- The `dynamic_testing` argument for all of these will be 13 – test-set results will then be in terms of rolling averages of 13-step forecasts, which is also our forecast length.
- The resulting forecasts from this process are not well-fit. Better forecasts are obtained once more optimization is performed in later sections.

1.1.4.1 Linear Scikit-Learn Models

[15]:
```
f.set_estimator('mlr')
f.manual_forecast(dynamic_testing=13)
```

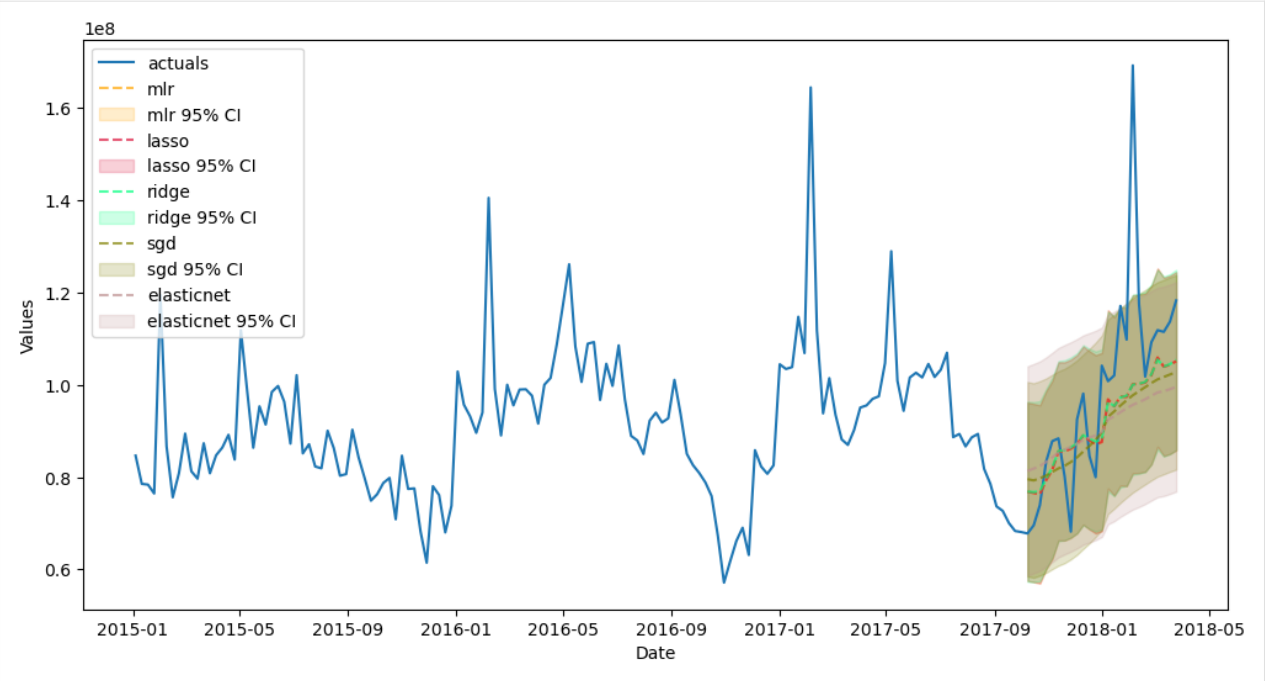
[16]:
```
f.set_estimator('lasso')
f.manual_forecast(alpha=0.2,dynamic_testing=13)
```

[17]:
```
f.set_estimator('ridge')
f.manual_forecast(alpha=0.2,dynamic_testing=13)
```

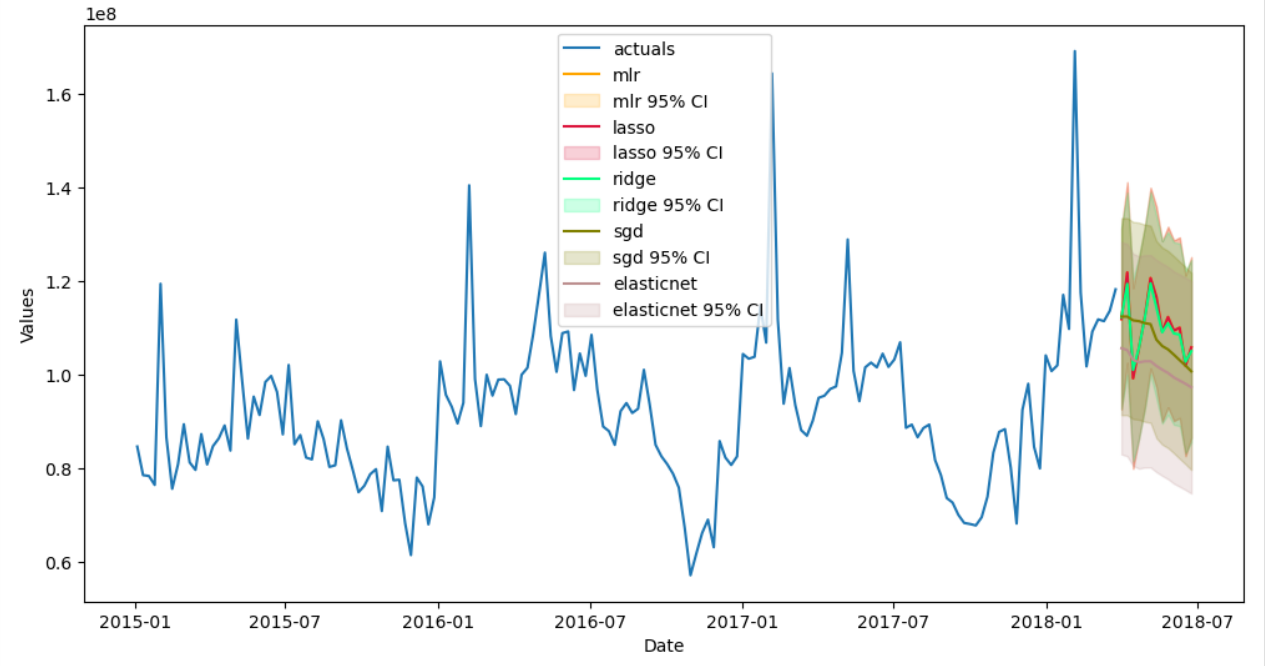
[18]:
```
f.set_estimator('elasticnet')
f.manual_forecast(alpha=0.2,l1_ratio=0.5,dynamic_testing=13)
```

[19]:
```
f.set_estimator('sgd')
f.manual_forecast(alpha=0.2,l1_ratio=0.5,dynamic_testing=13)
```

[20]:
```
f.plot_test_set(ci=True,models=['mlr','lasso','ridge','elasticnet','sgd'],order_by=
↪'TestSetRMSE')
plt.show()
```



[21]:
```
f.plot(ci=True,models=['mlr','lasso','ridge','elasticnet','sgd'],order_by='TestSetRMSE')
plt.show()
```



1.1.4.2 Non-linear Scikit-Learn Models

[22]:
```
f.set_estimator('rf')
f.manual_forecast(max_depth=2,dynamic_testing=13)
```

[23]:
```
f.set_estimator('gbt')
f.manual_forecast(max_depth=2,dynamic_testing=13)
```

[24]:
```
f.set_estimator('xgboost')
f.manual_forecast(gamma=1,dynamic_testing=13)
```

[25]:
```
f.set_estimator('lightgbm')
f.manual_forecast(max_depth=2,dynamic_testing=13)
```

[26]:
```
f.set_estimator('catboost')
f.manual_forecast(depth=4,verbose=False,dynamic_testing=13)
```

```
Finished loading model, total used 100 iterations
```

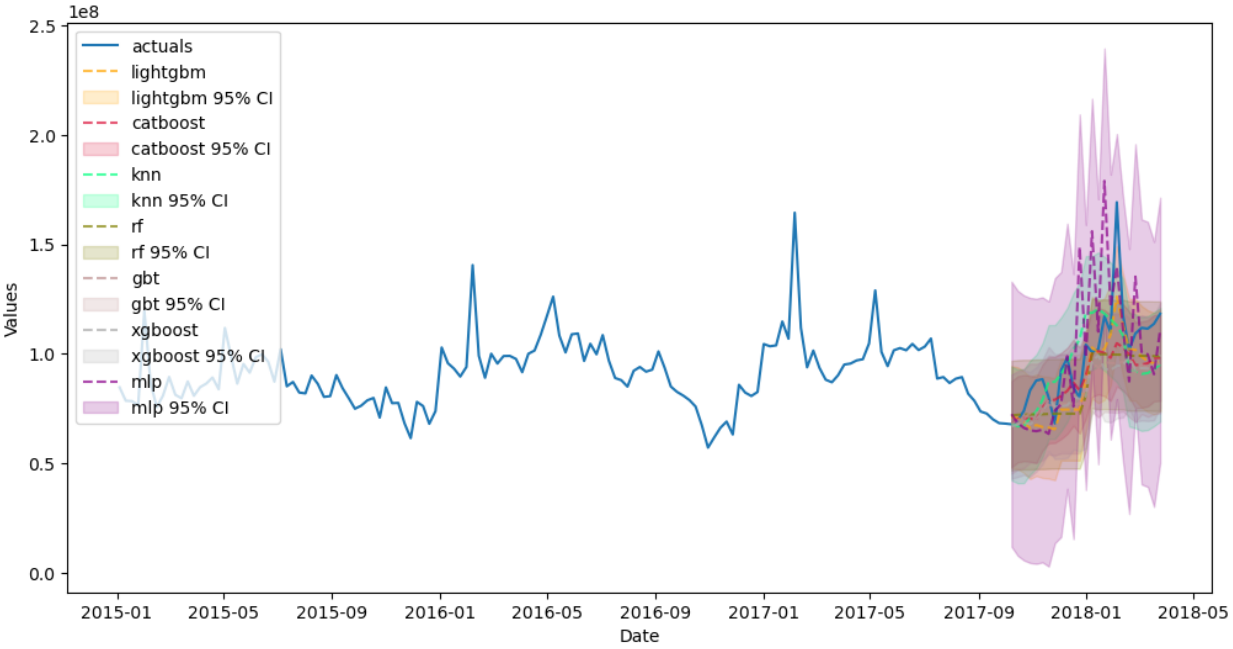
[27]:
```
f.set_estimator('knn')
f.manual_forecast(n_neighbors=5,dynamic_testing=13)
```

```
Finished loading model, total used 100 iterations
```

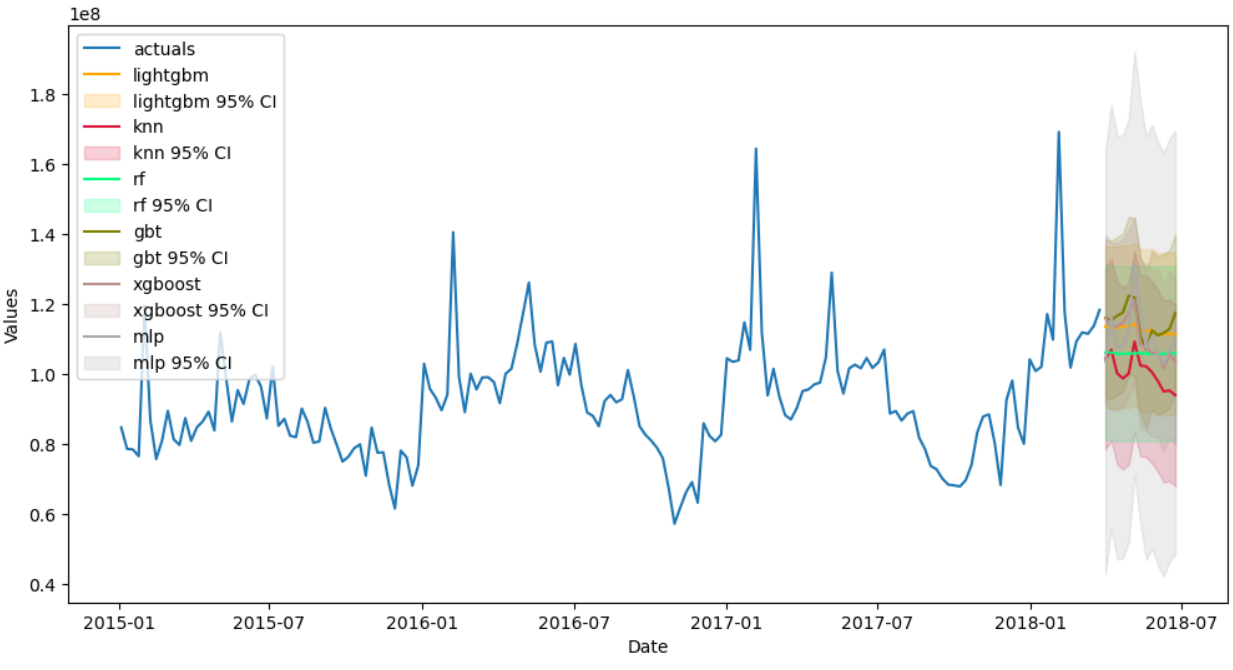
[28]:
```
f.set_estimator('mlp')
f.manual_forecast(hidden_layer_sizes=(50,50),solver='lbfgs',dynamic_testing=13)
```

```
Finished loading model, total used 100 iterations
```

[29]:
```
f.plot_test_set(
    ci=True,
    models=['rf','gbt','xgboost','lightgbm','catboost','knn','mlp'],
    order_by='TestSetRMSE'
)
plt.show()
```



[30]:
```
f.plot(ci=True,models=['rf','gbt','xgboost','lightgbm','knn','mlp'],order_by='TestSetRMSE
↪')
plt.show()
```



1.1.4.3 Stacking Models

Sklearn Stacking Model

[31]:
```
from sklearn.ensemble import StackingRegressor
from sklearn.linear_model import SGDRegressor
from sklearn.linear_model import ElasticNet
from sklearn.ensemble import GradientBoostingRegressor
from sklearn.neighbors import KNeighborsRegressor
from xgboost import XGBRegressor
from lightgbm import LGBMRegressor
```

[32]:
```
f.add_sklearn_estimator(StackingRegressor,'stacking')
```

[33]:
```
estimators = [
    ('elasticnet',ElasticNet(alpha=0.2)),
    ('xgboost',XGBRegressor(gamma=1)),
    ('gbt',GradientBoostingRegressor(max_depth=2)),
]

final_estimator = LGBMRegressor()

f.set_estimator('stacking')
f.manual_forecast(
    estimators=estimators,
    final_estimator=final_estimator,
    dynamic_testing=13
)
```

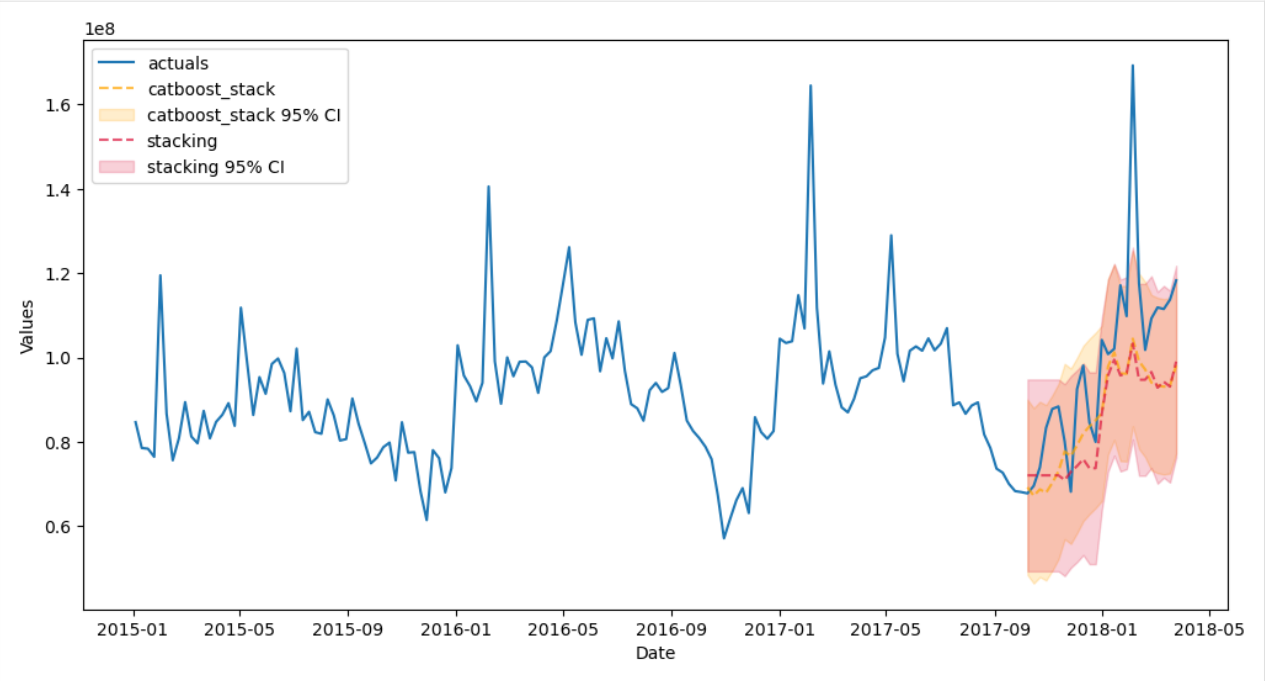
```
Finished loading model, total used 100 iterations
```

Scalecast Stacking Model

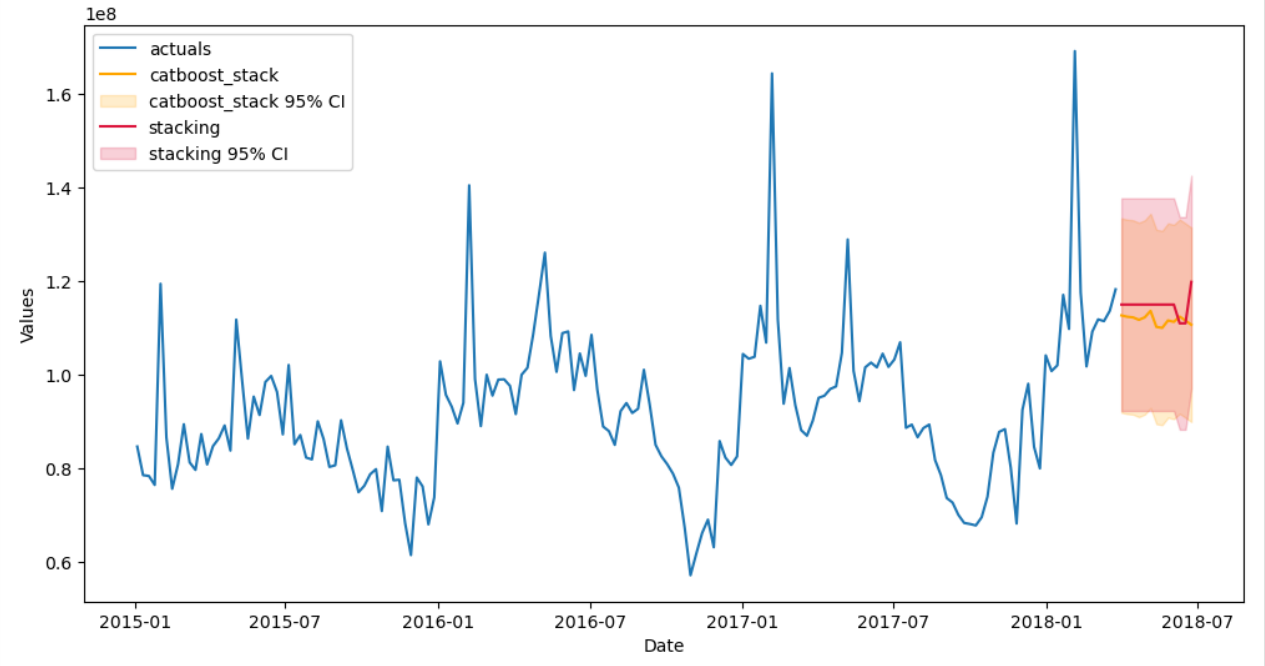
[34]:
```
f.add_signals(['elasticnet','lightgbm','xgboost','knn'],train_only=True)
f.set_estimator('catboost')
f.manual_forecast(call_me = 'catboost_stack',verbose=False)
```

```
Finished loading model, total used 100 iterations
Finished loading model, total used 100 iterations
```

[35]:
```
f.plot_test_set(models=['stacking','catboost_stack'],ci=True,order_by='TestSetRMSE')
plt.show()
```



[36]:
```
f.plot(models=['stacking','catboost_stack'],ci=True,order_by='TestSetRMSE')
plt.show()
```



1.1.4.4 ARIMA

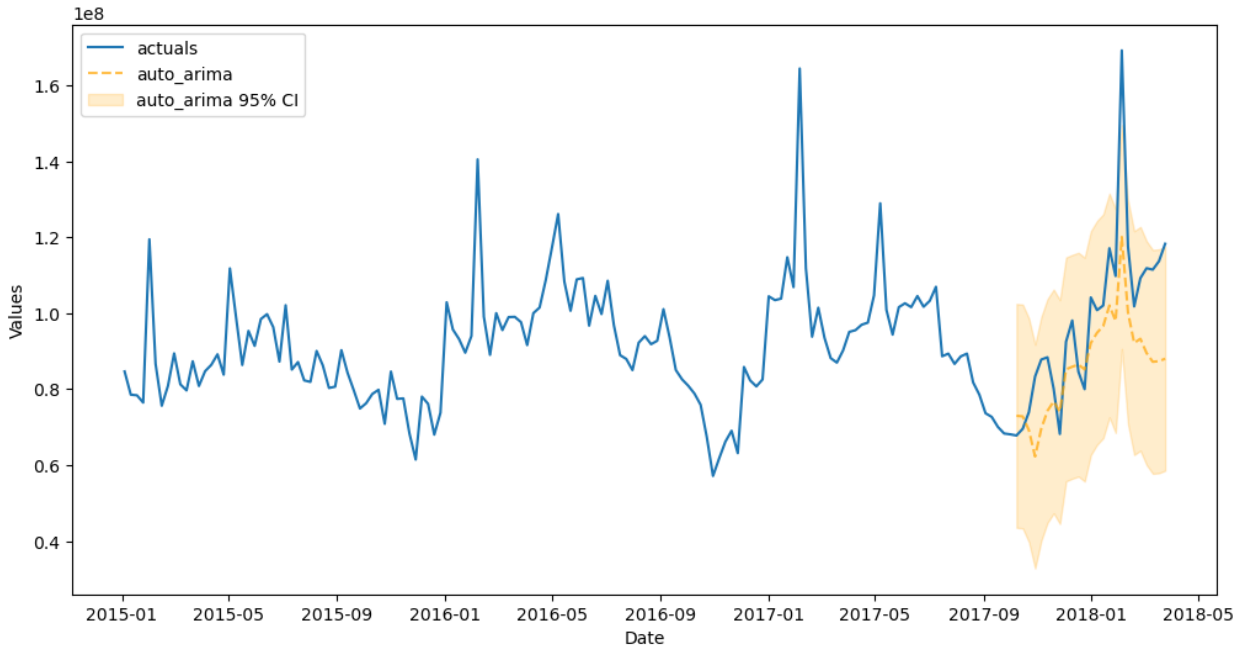
- auxmodels.auto_arima

[37]:
```
from scalecast.auxmodels import auto_arima
```

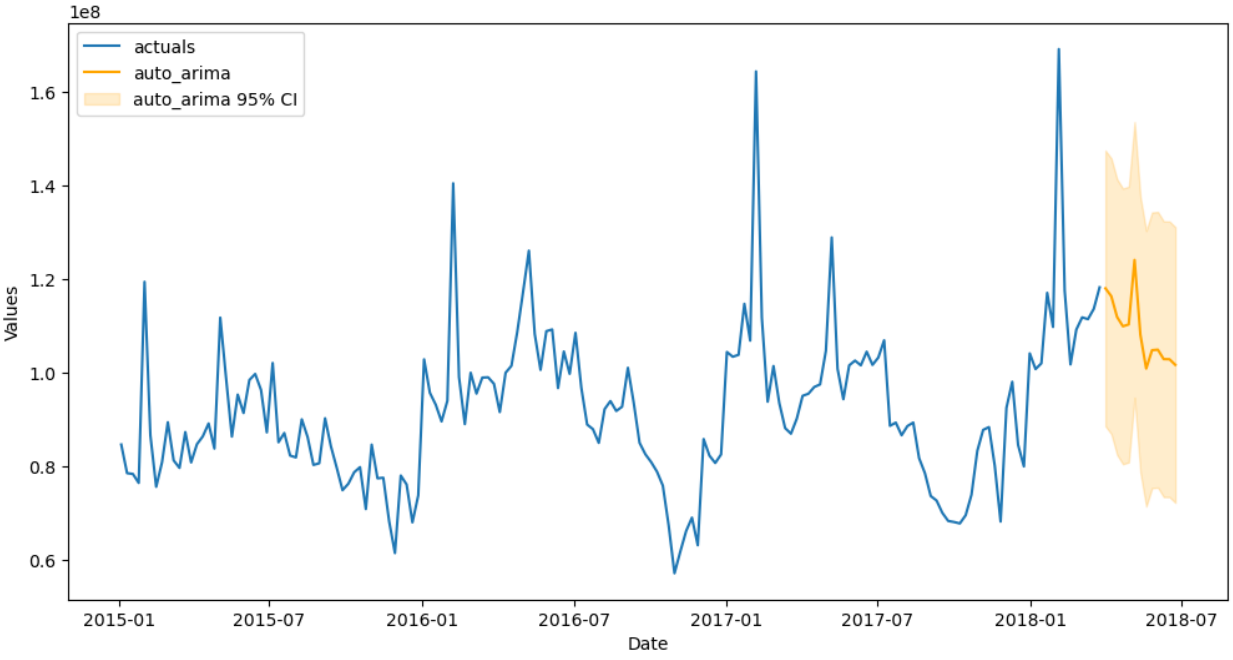
[38]:
```
auto_arima(f,m=52)
```

```
Finished loading model, total used 100 iterations
Finished loading model, total used 100 iterations
```

[39]:
```
f.plot_test_set(models='auto_arima',ci=True)
plt.show()
```



[40]:
```
f.plot(models='auto_arima',ci=True)
plt.show()
```



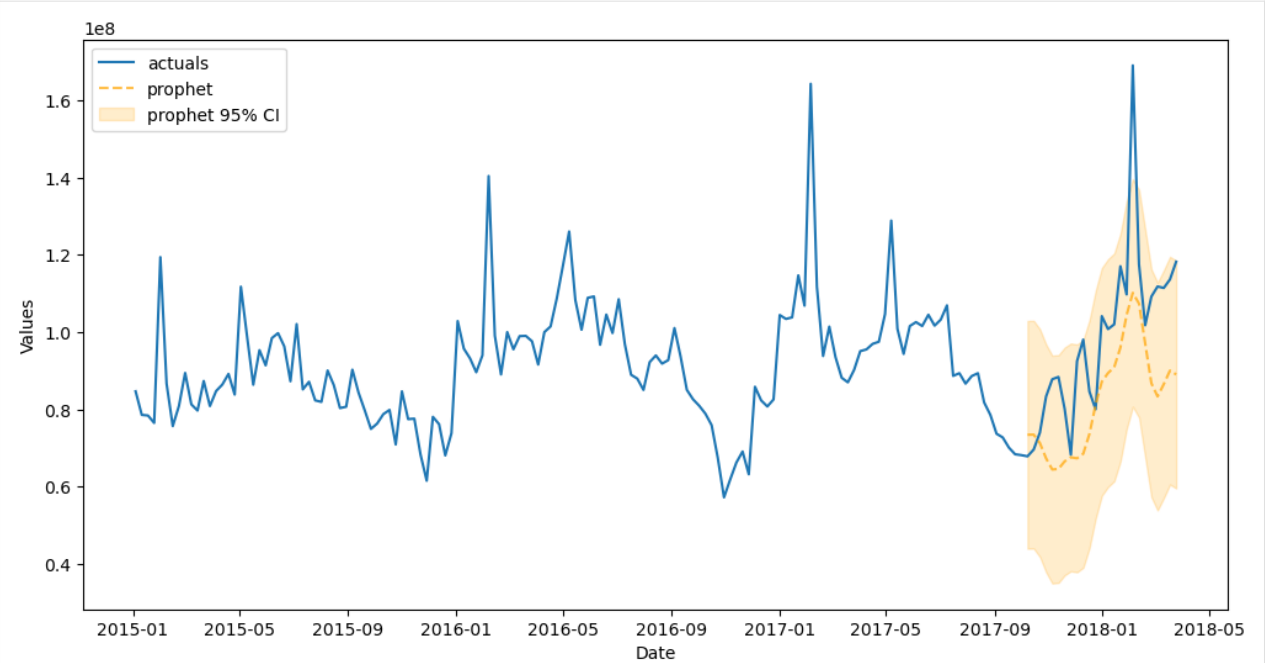
1.1.4.5 Prophet

[41]:
```
f.set_estimator('prophet')
f.manual_forecast()
```

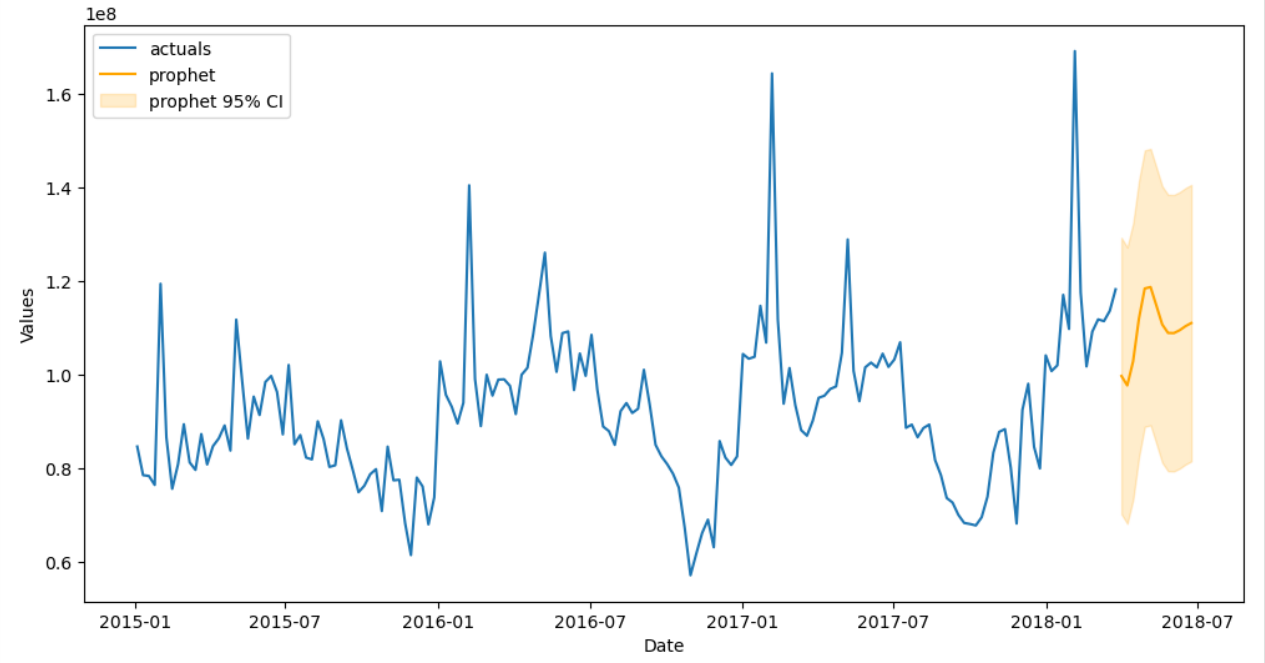
```
Finished loading model, total used 100 iterations
Finished loading model, total used 100 iterations
```

```
22:14:17 - cmdstanpy - INFO - Chain [1] start processing
22:14:17 - cmdstanpy - INFO - Chain [1] done processing
22:14:17 - cmdstanpy - INFO - Chain [1] start processing
22:14:17 - cmdstanpy - INFO - Chain [1] done processing
```

[42]:
```
f.plot_test_set(models='prophet',ci=True)
plt.show()
```



[43]:
```
f.plot(models='prophet',ci=True)
plt.show()
```



Other univariate models available: TBATS, Holt-Winters Exponential Smoothing, LSTM, RNN, Silverkite, Theta.

Working on: N-Beats, N-Hits, Genetic Algorithm.

1.2 Multivariate Forecasting

1.2.1 Load the `MVForecaster` Object

- This object extends the univariate approach to several series, with many of the same plotting and reporting features available.
- Documentation

[44]:
```
from scalecast.MVForecaster import MVForecaster
```

[45]:
```
price = data.groupby('Date')['AveragePrice'].mean()

fvol = Forecaster(y=volume,current_dates=volume.index,future_dates=13)
fprice = Forecaster(y=price,current_dates=price.index,future_dates=13)

fvol.add_time_trend()
fvol.add_seasonal_regressors('week',raw=False,sincos=True)

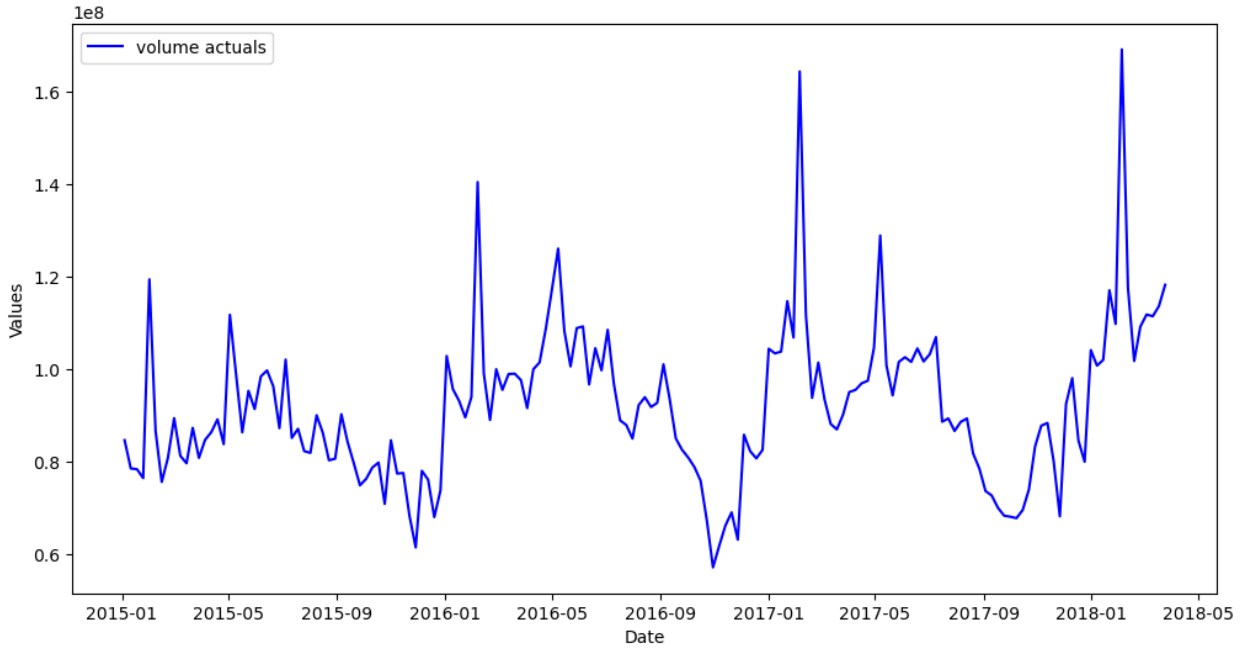
mvf = MVForecaster(
    fvol,
    fprice,
    merge_Xvars='union',
    names=['volume','price'],
)

mvf
```

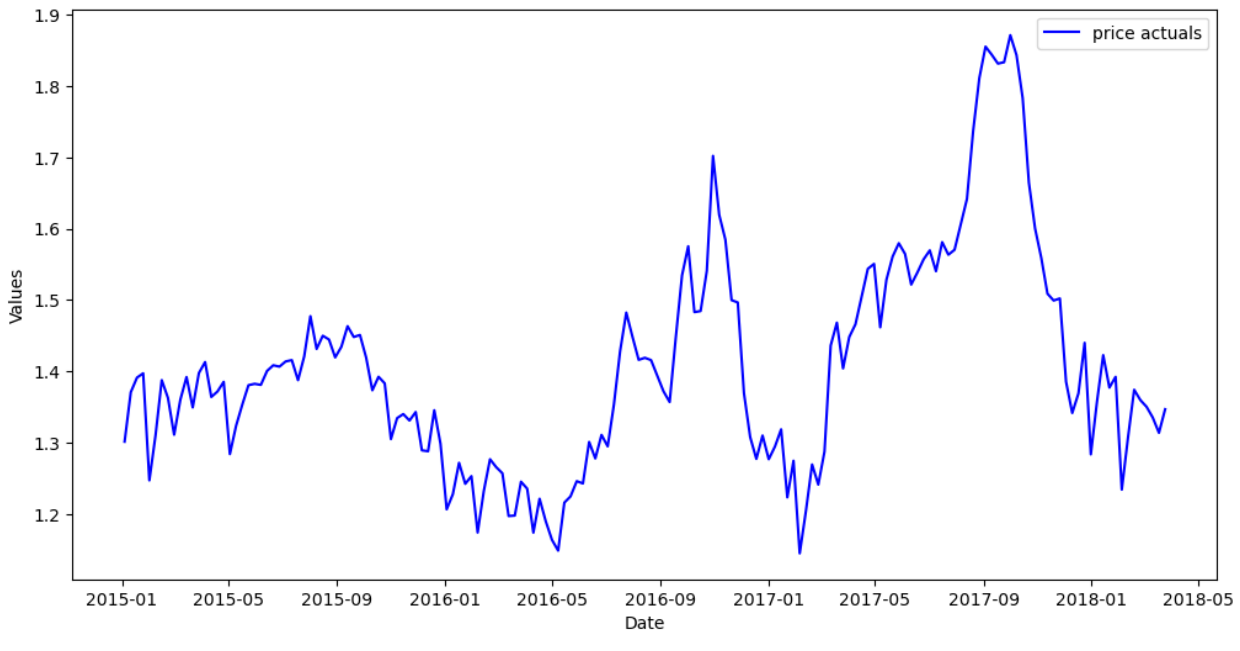
[45]:
```
MVForecaster(
    DateStartActuals=2015-01-04T00:00:00.000000000
    DateEndActuals=2018-03-25T00:00:00.000000000
    Freq=W-SUN
    N_actuals=169
    N_series=2
    SeriesNames=['volume', 'price']
    ForecastLength=13
    Xvars=['t', 'weeksin', 'weekcos']
    TestLength=0
    ValidationLength=1
    ValidationMetric=rmse
    ForecastsEvaluated=[]
    CILevel=None
    CurrentEstimator=mlr
    OptimizeOn=mean
    GridsFile=MVGrids
)
```

1.2.2 Exploratory Data Analysis

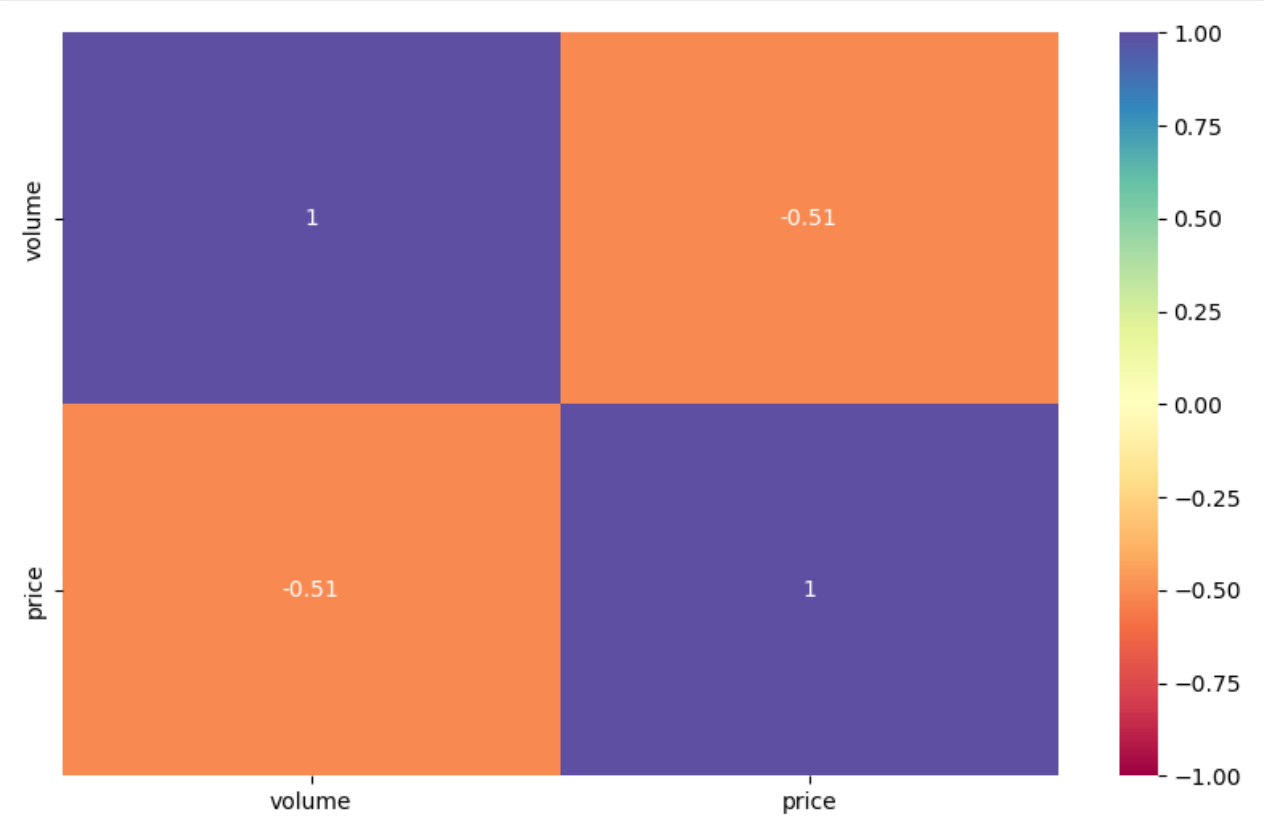
[46]:
```
mvf.plot(series='volume')
plt.show()
```



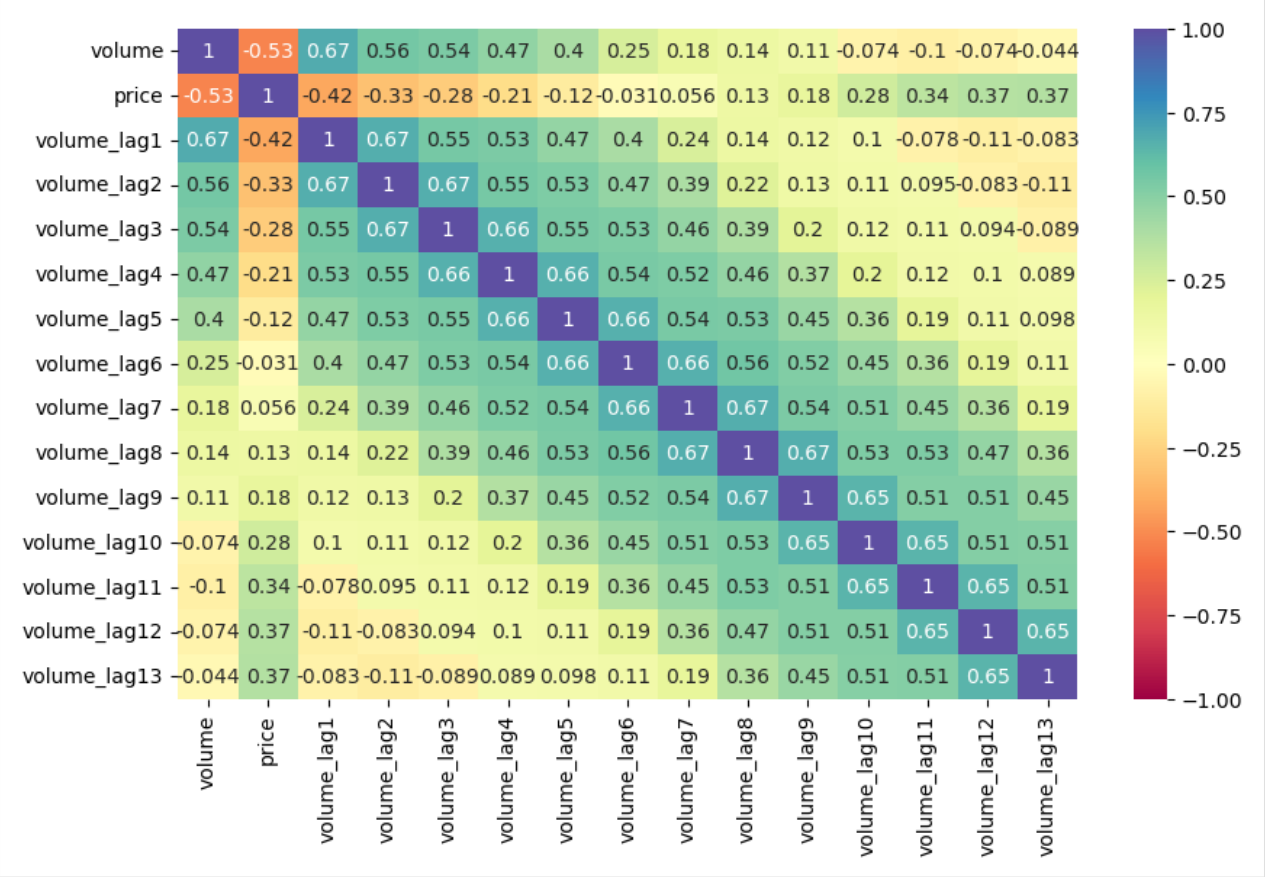
[47]:
```
mvf.plot(series='price')
plt.show()
```



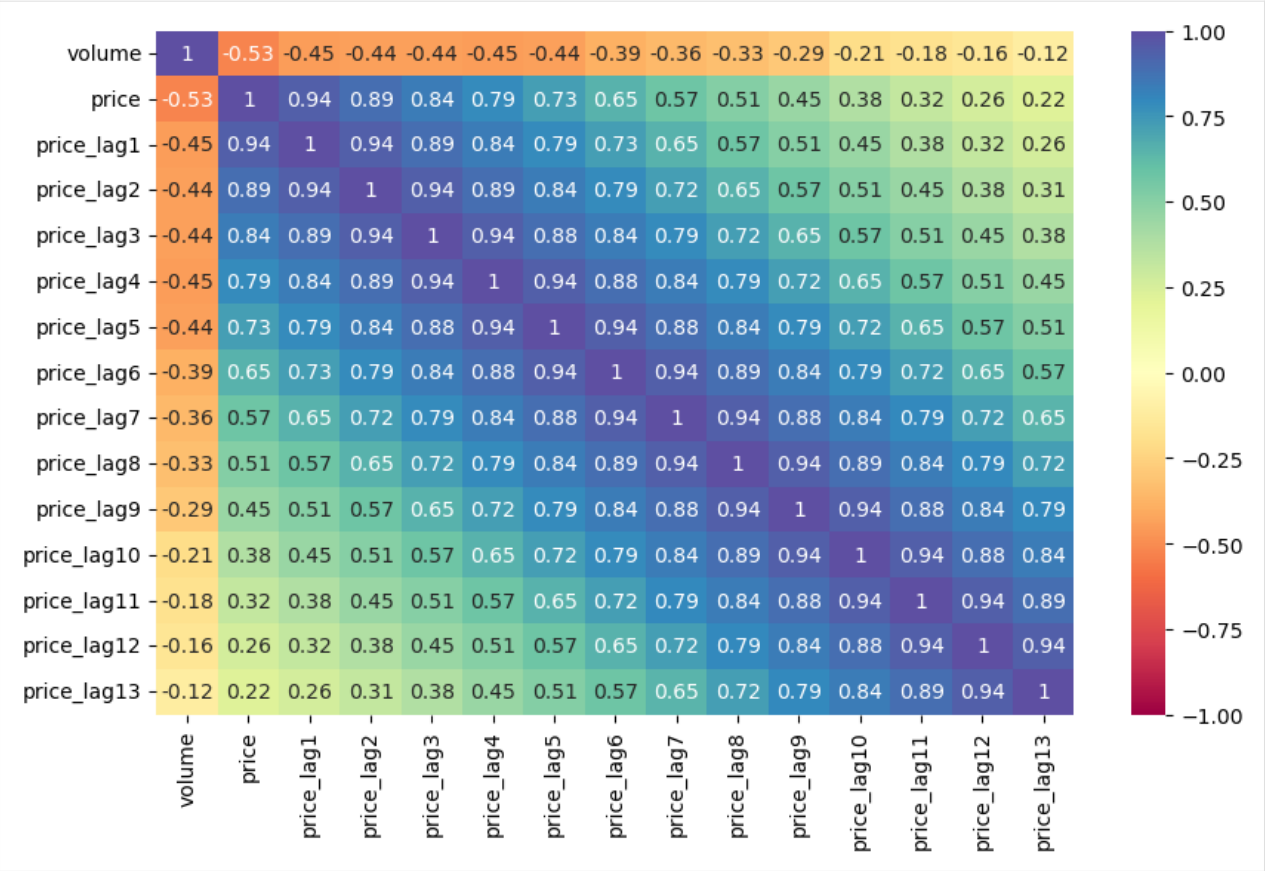
[48]:
```
mvf.corr(disp='heatmap',cmap='Spectral',annot=True,vmin=-1,vmax=1)
plt.show()
```



[49]:
```
mvf.corr_lags(y='price',x='volume',disp='heatmap',cmap='Spectral',annot=True,vmin=-1,
↪vmax=1,lags=13)
plt.show()
```



[50]:
```
mvf.corr_lags(y='volume',x='price',disp='heatmap',cmap='Spectral',annot=True,vmin=-1,
↪vmax=1,lags=13)
plt.show()
```



1.2.3 Parameterize the `MVForecaster` Object

- Starting in scalecast version 0.16.0, you can skip model testing by setting a test length of 0.
- In this example, all models will be tested on the last 15% of the observed values in the dataset.
- We will also have model optimization select hyperparemeters based on what predicts the volume series, rather than the price series, or an average of the two (which is the default), best.
- Custom optimization functions are available.

[51]:
```
mvf.set_test_length(.15)
mvf.set_optimize_on('volume') # we care more about predicting volume and price is just␣
↪used to make those predictions more accurate
# by default, the optimizer uses an average scoring of all series in the MVForecaster␣
↪object
mvf.eval_cis() # tell object to evaluate cis

mvf
```

[51]:
```
MVForecaster(
    DateStartActuals=2015-01-04T00:00:00.000000000
    DateEndActuals=2018-03-25T00:00:00.000000000
    Freq=W-SUN
    N_actuals=169
    N_series=2
```

(continues on next page)

(continued from previous page)

```
    SeriesNames=['volume', 'price']
    ForecastLength=13
    Xvars=['t', 'weeksin', 'weekcos']
    TestLength=25
    ValidationLength=1
    ValidationMetric=rmse
    ForecastsEvaluated=[]
    CILevel=0.95
    CurrentEstimator=mlr
    OptimizeOn=volume
    GridsFile=MVGrids
)
```

1.2.4 Run Models

- Uses scikit-learn models and APIs only.
- See the adapted VECM model for this object.

1.2.4.1 ElasticNet

[52]:
```
mvf.set_estimator('elasticnet')
mvf.manual_forecast(alpha=0.2,dynamic_testing=13,lags=13)
```

1.2.4.2 XGBoost

[53]:
```
mvf.set_estimator('xgboost')
mvf.manual_forecast(gamma=1,dynamic_testing=13,lags=13)
```

1.2.4.3 MLP Stack

- auxmodels.mlp_stack

[54]:
```
from scalecast.auxmodels import mlp_stack
```

[55]:
```
mvf.export('model_summaries')
```

[55]:
```
   Series ModelNickname   Estimator                 Xvars     HyperParams  \
0  volume    elasticnet  elasticnet  [t, weeksin, weekcos]  {'alpha': 0.2}
1  volume       xgboost     xgboost  [t, weeksin, weekcos]    {'gamma': 1}
2   price    elasticnet  elasticnet  [t, weeksin, weekcos]  {'alpha': 0.2}
3   price       xgboost     xgboost  [t, weeksin, weekcos]    {'gamma': 1}

   Lags  Observations  DynamicallyTested  TestSetLength  ValidationMetric  \
0    13           169                 13             25               NaN
1    13           169                 13             25               NaN
2    13           169                 13             25               NaN
3    13           169                 13             25               NaN
```

(continues on next page)

(continued from previous page)

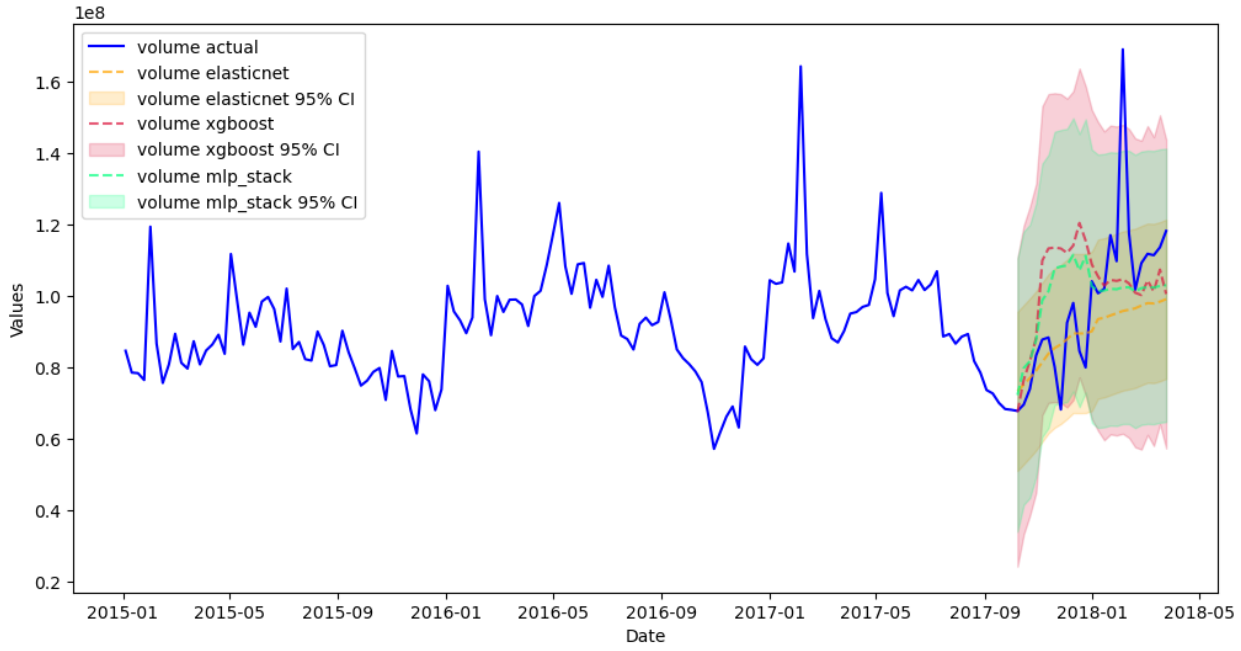
```
   ValidationMetricValue  InSampleRMSE  InSampleMAPE   InSampleMAE  \
0                    NaN  1.197603e+07      0.088917  8.206334e+06
1                    NaN  3.416022e+02      0.000003  2.591667e+02
2                    NaN  1.560728e-01      0.084080  1.199107e-01
3                    NaN  1.141005e-01      0.058215  8.255353e-02

   InSampleR2   TestSetRMSE  TestSetMAPE    TestSetMAE  TestSetR2
0    0.486109  1.869490e+07     0.118172  1.282436e+07   0.248765
1    1.000000  2.260606e+07     0.173554  1.644149e+07  -0.098447
2    0.000000  1.522410e-01     0.071282  1.088633e-01  -0.048569
3    0.465533  1.291758e-01     0.057186  8.791148e-02   0.245089
```

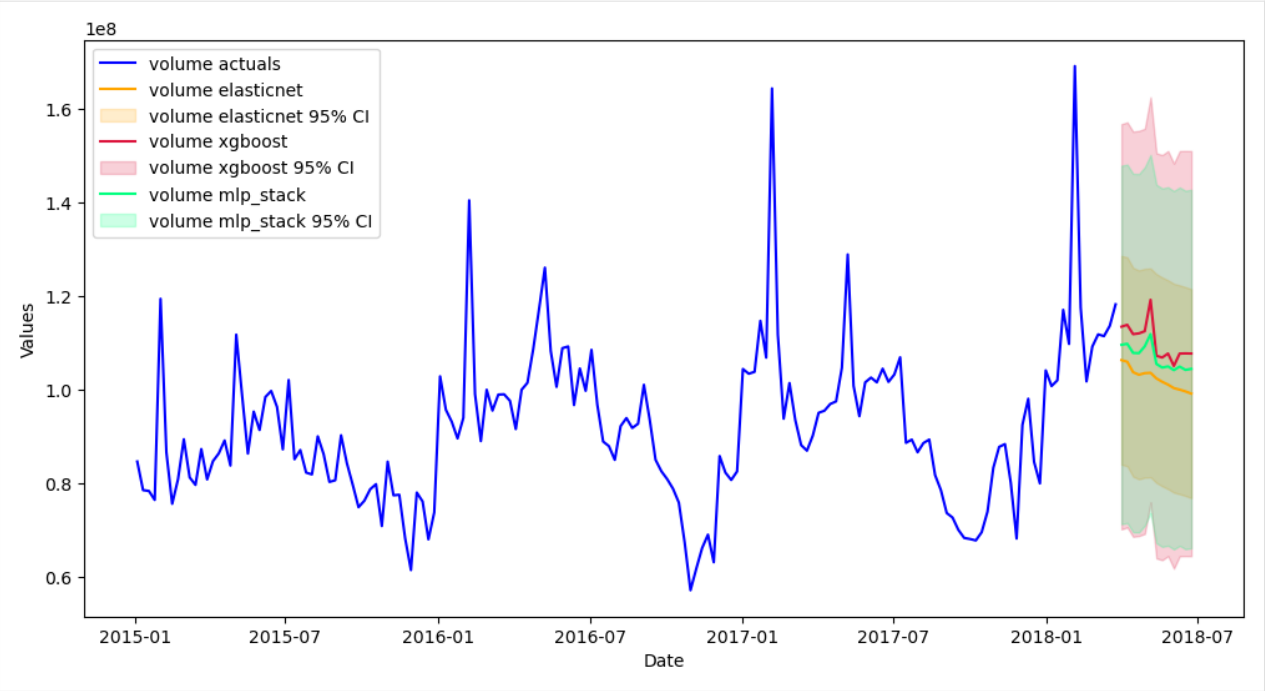
[56]:
```
mlp_stack(mvf,model_nicknames=['elasticnet','xgboost'],lags=13)
```

[57]:
```
mvf.set_best_model(determine_best_by='TestSetRMSE')
```

[58]:
```
mvf.plot_test_set(ci=True,series='volume',put_best_on_top=True)
plt.show()
```

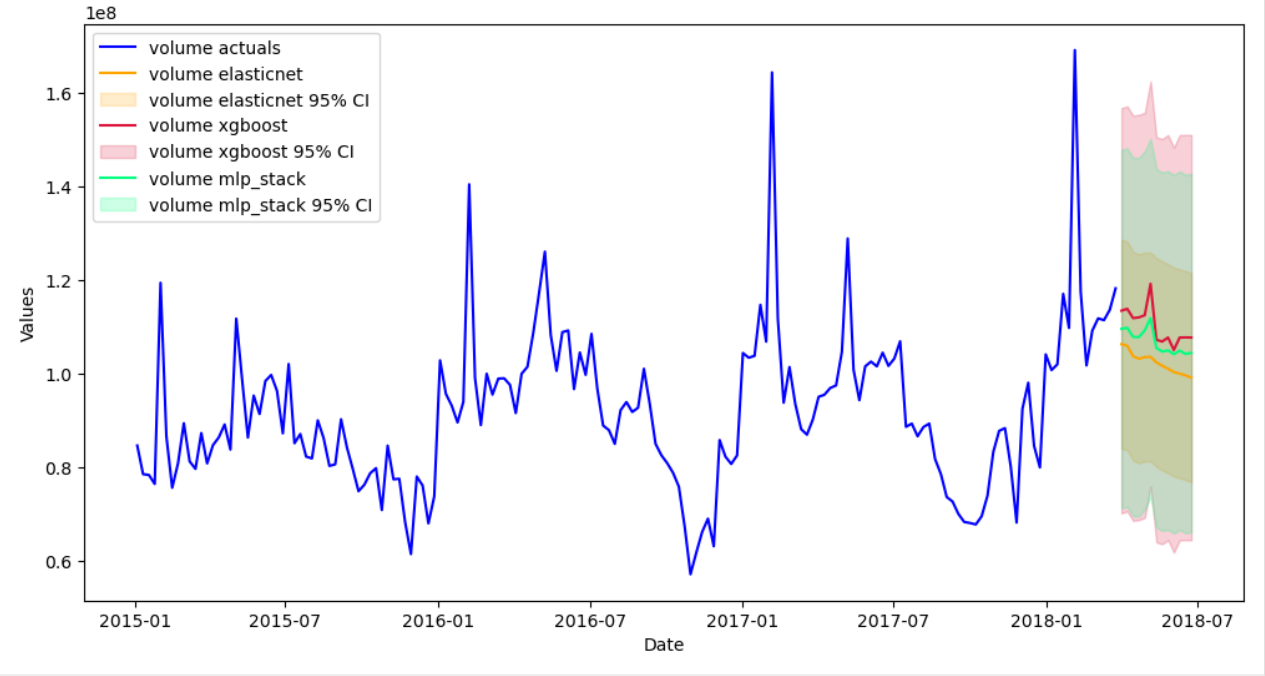


[59]:
```
mvf.plot(ci=True,series='volume',put_best_on_top=True)
plt.show()
```



Probabalistic forecasting for creating confidence intervals is currently being worked on in the MVForecaster object, but until that is done, the backtested interval also works well:

[60]:
```
mvf.plot(ci=True,series='volume',put_best_on_top=True)
plt.show()
```



1.2.5 Break Back into Forecaster Objects

- You can then add univariate models to these objects to compare with the models run multivariate.

[61]:
```
from scalecast.util import break_mv_forecaster
```

[62]:
```
fvol, fprice = break_mv_forecaster(mvf)
```

[63]:
```
fvol
```

[63]:
```
Forecaster(
    DateStartActuals=2015-01-04T00:00:00.000000000
    DateEndActuals=2018-03-25T00:00:00.000000000
    Freq=W-SUN
    N_actuals=169
    ForecastLength=13
    Xvars=[]
    TestLength=25
    ValidationMetric=rmse
    ForecastsEvaluated=['elasticnet', 'xgboost', 'mlp_stack']
    CILevel=0.95
    CurrentEstimator=mlr
    GridsFile=Grids
)
```

[64]:
```
fprice
```

[64]:
```
Forecaster(
    DateStartActuals=2015-01-04T00:00:00.000000000
    DateEndActuals=2018-03-25T00:00:00.000000000
    Freq=W-SUN
    N_actuals=169
    ForecastLength=13
    Xvars=[]
    TestLength=25
    ValidationMetric=rmse
    ForecastsEvaluated=['elasticnet', 'xgboost', 'mlp_stack']
    CILevel=0.95
    CurrentEstimator=mlr
    GridsFile=Grids
)
```

1.3 Transformations

- One of the most effective way to boost forecasting power is with transformations.
- Transformations include:
- Log
- Scaling
  - Standard
  - MinMax

- Differencing
- Detrending
- Custom Functions
- All transformations have a corresponding revert function.
- See the blog post.

[65]:
```
from scalecast.SeriesTransformer import SeriesTransformer
```

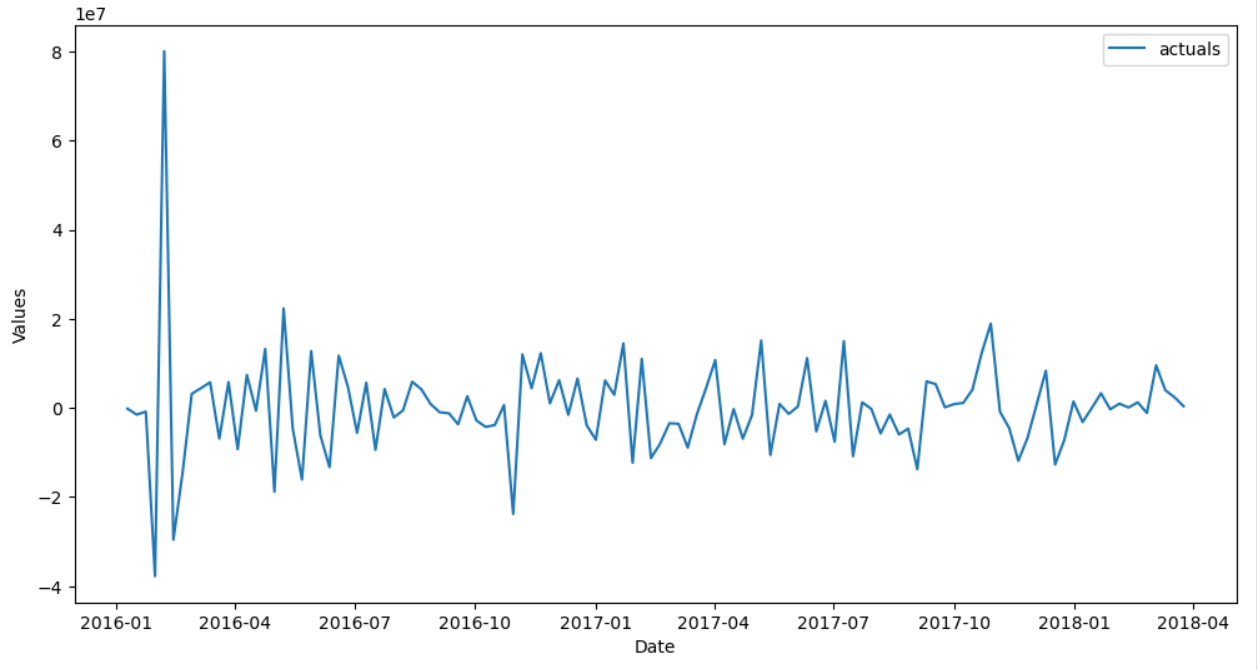
[66]:
```
f_trans = Forecaster(y=volume,current_dates=volume.index,future_dates=13)
```

[67]:
```
f_trans.set_test_length(.15)
f_trans.set_validation_length(13)
```

[68]:
```
transformer = SeriesTransformer(f_trans)
```

[69]:
```
# these will all be reverted later after forecasts have been called
f_trans = transformer.DiffTransform(1)
f_trans = transformer.DiffTransform(52)
f_trans = transformer.DetrendTransform()
```

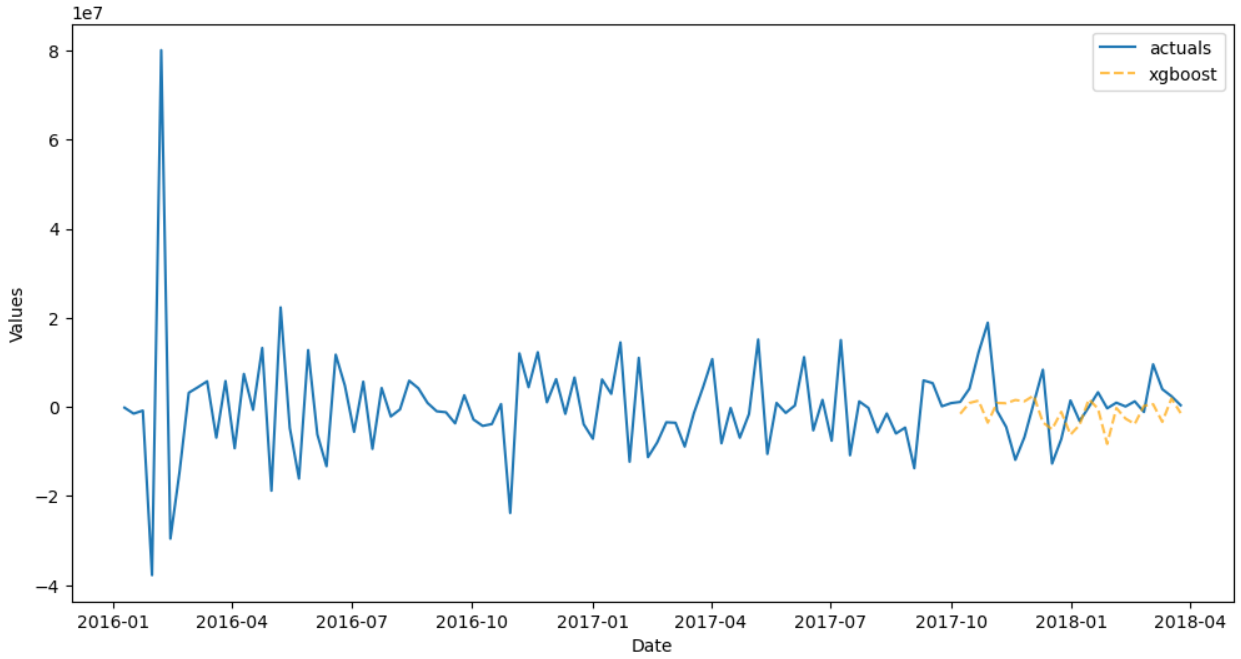
[70]:
```
f_trans.plot()
plt.show()
```



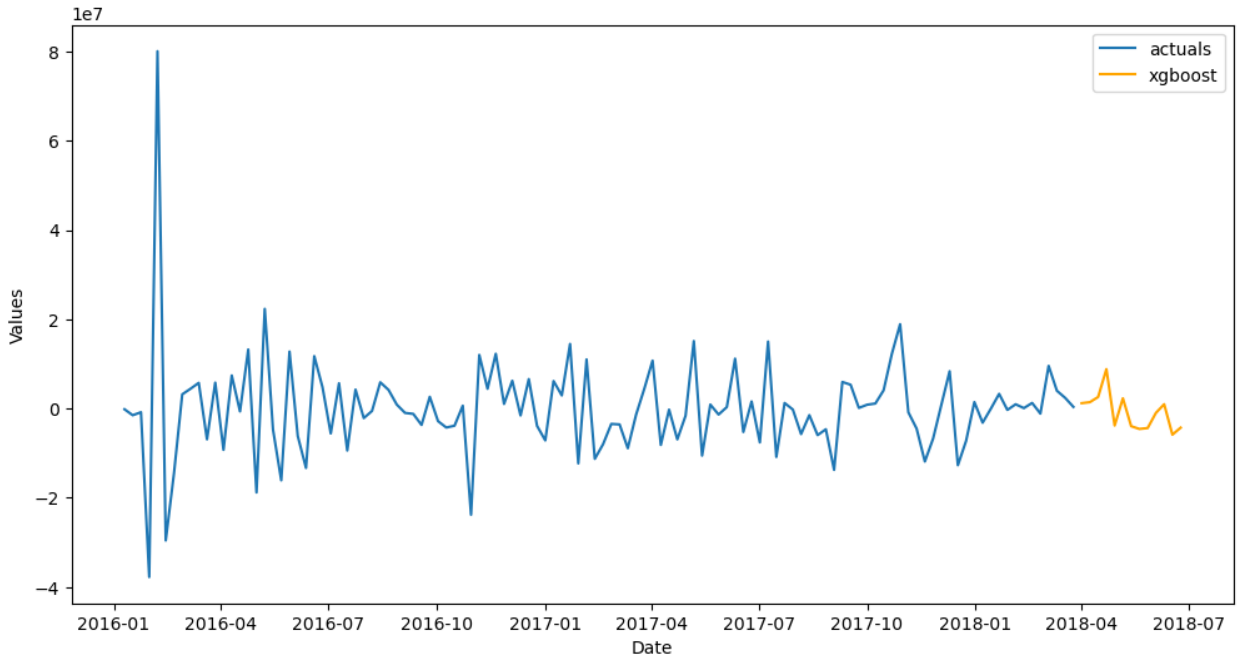
[71]:
```
f_trans.add_time_trend()
f_trans.add_seasonal_regressors('week',sincos=True,raw=False)
f_trans.add_ar_terms(13)
```

[72]:
```
f_trans.set_estimator('xgboost')
f_trans.manual_forecast(gamma=1,dynamic_testing=13)
```

[73]:
```
f_trans.plot_test_set()
plt.show()
```

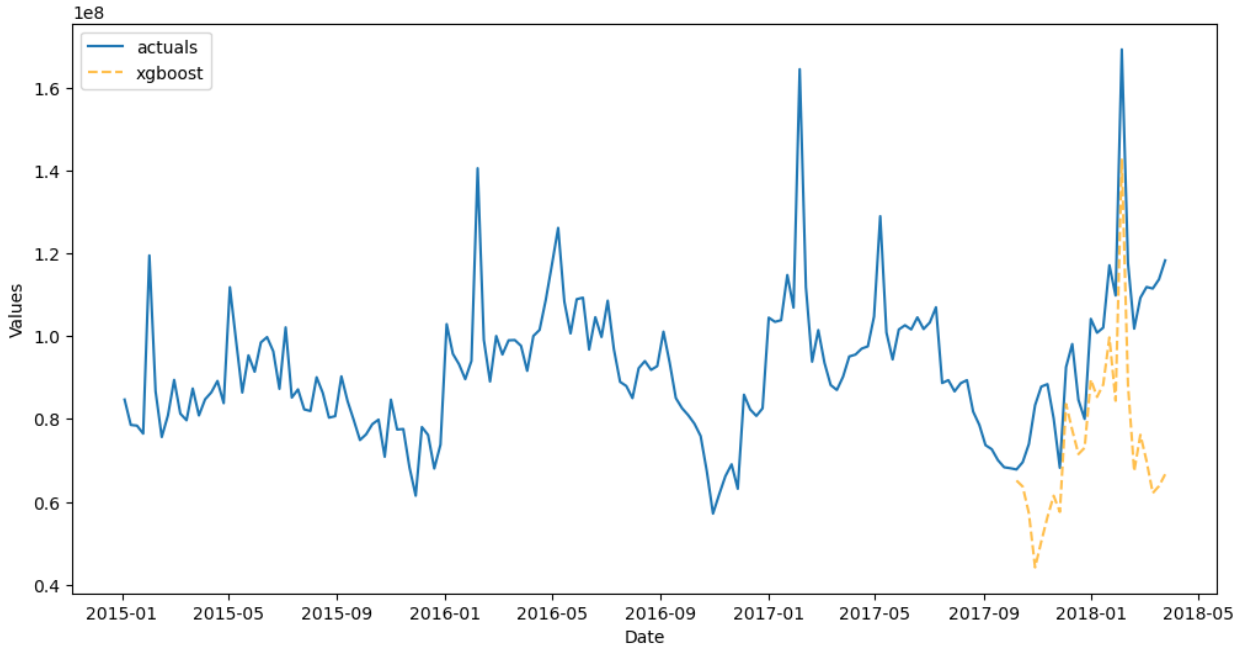


[74]:
```
f_trans.plot()
plt.show()
```

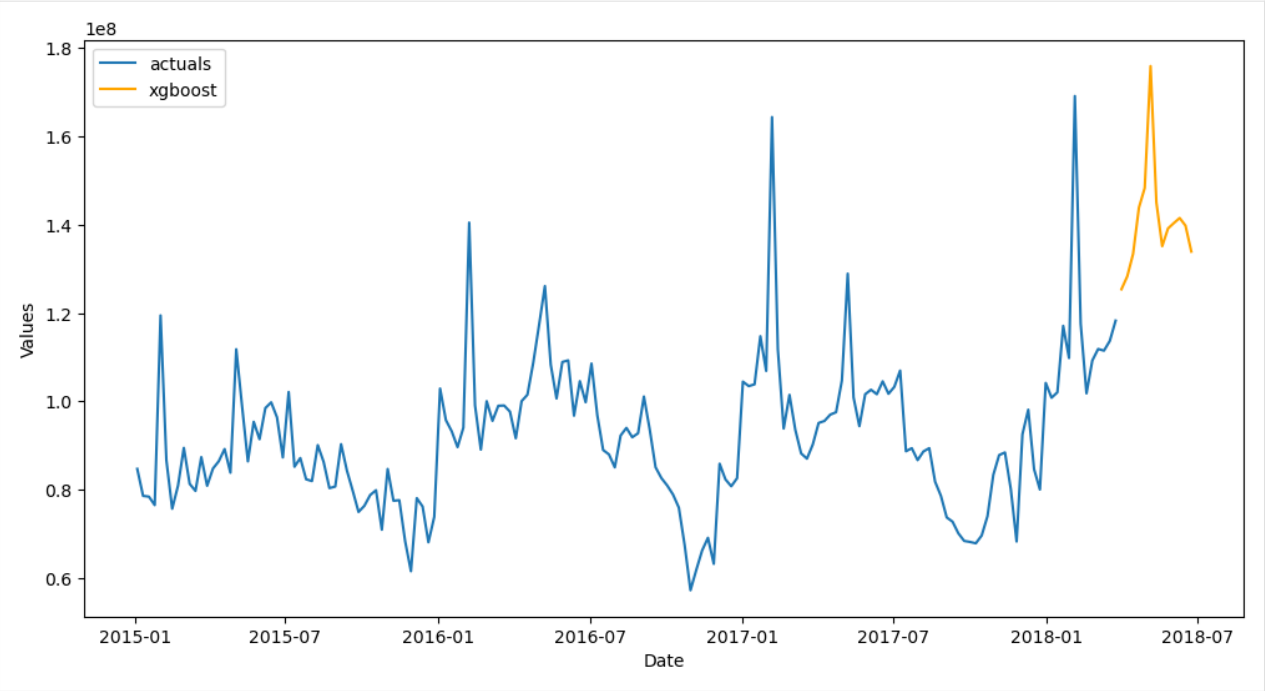


[75]:
```
# call revert functions in the opposite order as how they were called when transforming
f_trans = transformer.DetrendRevert()
f_trans = transformer.DiffRevert(52)
f_trans = transformer.DiffRevert(1)
```

[76]:
```
f_trans.plot_test_set()
plt.show()
```



[77]:
```
f_trans.plot()
plt.show()
```



1.4 Pipelines

- These are objects similar to scikit-learn pipelines that offer readable and streamlined code for transforming, forecasting, and reverting.
- See the Pipeline object documentation.

[78]:
```
from scalecast.Pipeline import Transformer, Reverter, Pipeline, MVPipeline
```

[79]:
```
f_pipe = Forecaster(y=volume,current_dates=volume.index,future_dates=13)
f_pipe.set_test_length(.15)
```

[80]:
```
def forecaster(f):
    f.add_time_trend()
    f.add_seasonal_regressors('week',raw=False,sincos=True)
    f.add_ar_terms(13)
    f.set_estimator('lightgbm')
    f.manual_forecast(max_depth=2)
```

[81]:
```
transformer = Transformer(
    transformers = [
        ('DiffTransform',1),
        ('DiffTransform',52),
        ('DetrendTransform',)
    ]
)

reverter = Reverter(
```

(continues on next page)

(continued from previous page)

```
    reverters = [
        ('DetrendRevert',),
        ('DiffRevert',52),
        ('DiffRevert',1)
    ],
    base_transformer = transformer,
)
```

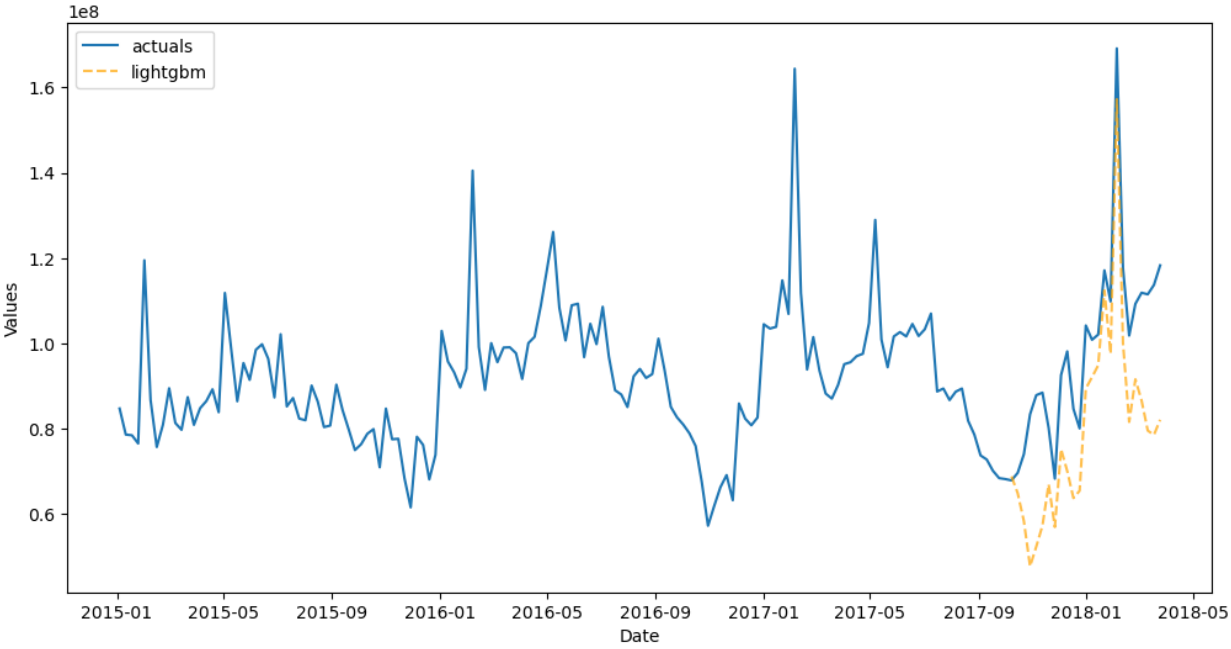
[82]:
```
reverter
```

[82]:
```
Reverter(
  reverters = [
    ('DetrendRevert',),
    ('DiffRevert', 52),
    ('DiffRevert', 1)
  ],
  base_transformer = Transformer(
  transformers = [
    ('DiffTransform', 1),
    ('DiffTransform', 52),
    ('DetrendTransform',)
  ]
)
)
```

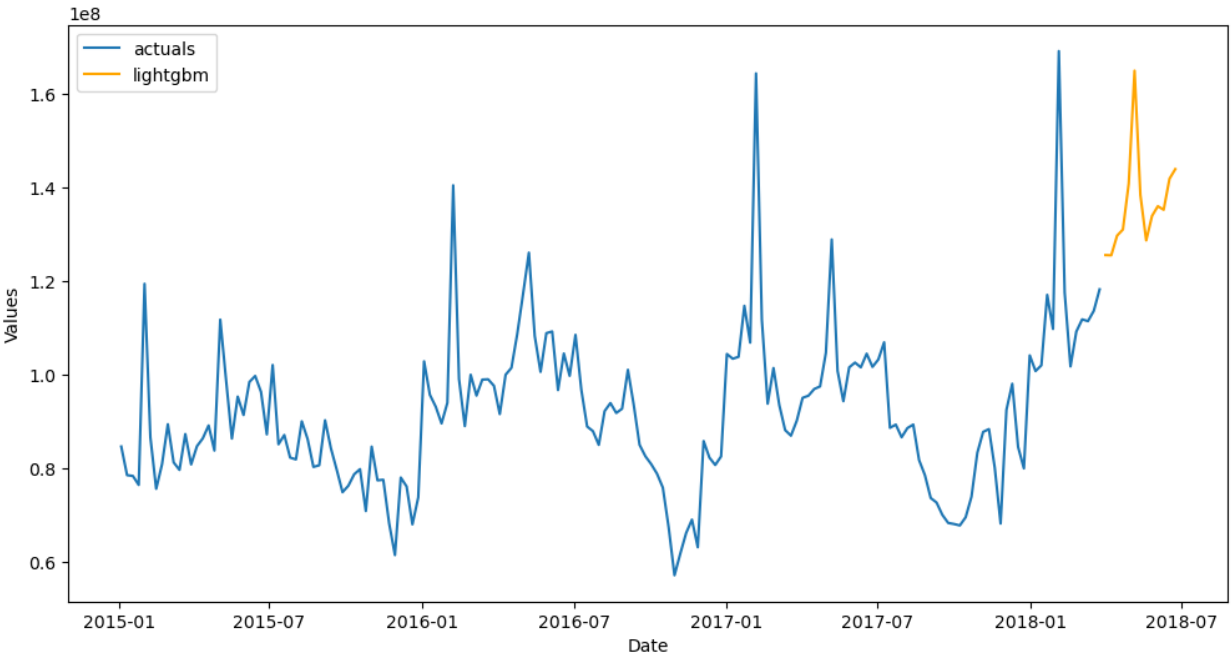
[83]:
```
pipeline = Pipeline(
    steps = [
        ('Transform',transformer),
        ('Forecast',forecaster),
        ('Revert',reverter),
    ]
)

f_pipe = pipeline.fit_predict(f_pipe)
```

[84]:
```
f_pipe.plot_test_set()
plt.show()
```



[85]:
```
f_pipe.plot()
plt.show()
```



1.5 Fully Automated Pipelines

- We can automate the construction of pipelines, the selection of input variables, and tuning of models with cross validation on a grid search for each model using files in the working directory called `Grids.py` for univariate forecasting and `MVGrids.py` for multivariate. Default grids can be downloaded from scalecast.

1.5.1 Automated Univariate Pipelines

- Documentation

[86]:
```
from scalecast import GridGenerator
from scalecast.util import find_optimal_transformation
```

[87]:
```
GridGenerator.get_example_grids(overwrite=True)
```

[88]:
```
f_pipe_aut = Forecaster(y=volume,current_dates=volume.index,future_dates=13)
f_pipe_aut.set_test_length(.15)
```

[89]:
```
def forecaster_aut(f,models):
    f.auto_Xvar_select(
        estimator='elasticnet',
        monitor='TestSetMAE',
        alpha=0.2,
        irr_cycles = [26],
    )
    f.tune_test_forecast(
        models,
        cross_validate=True,
        k=3,
        # dynamic tuning = 13 means we will hopefully find a model that is optimized to␣
↪predict 13 steps
        dynamic_tuning=13,
        dynamic_testing=13,
    )
    f.set_estimator('combo')
    f.manual_forecast()
```

1.5.2 util.find_optimal_transformation

In this function, the following transformations are searched for:
- Detrending
- Box-Cox
- First Differencing
- Seasonal Differencing
- Scaling

The optimal set of transformations are returned based on best estimated out-of-sample performance on the test set. Therefore, running this function introduces leakage into the test set, but it can still be a good addition to an automated pipeline, depending on the application. Which and the order of transfomations to search through are configurable.

How performance is measured, the parameters specific to a given transformation, and several other paramters are also configurable. See the documentation.

[90]:
```
transformer_aut, reverter_aut = find_optimal_transformation(
    f_pipe_aut,
    lags = 13,
    m = 52,
    monitor = 'mae',
    estimator = 'elasticnet',
    alpha = 0.2,
    test_length = 13,
    num_test_sets = 3,
    space_between_sets = 4,
    verbose = True,
) # returns a Transformer and Reverter object that can be plugged into a larger pipeline
```

```
All transformation tries will use 13 lags.

1.5.3 Backtest Univariate Pipeline

You may be interested to know beyond a single test-set metric, how well your pipeline performs out-of-sample. Backtesting can help answer that by iterating through the entire pipeline several times and testing the procedure each time. It can also help make expanding confidence intervals. See the documentation.

[95]:
```
from scalecast.util import backtest_metrics
```

[96]:
```
uv_backtest_results = pipeline_aut.backtest(
    f_pipe_aut,
    n_iter = 3,
    jump_back = 13,
    cis = False,
    models=[
        'mlr',
        'elasticnet',
        'xgboost',
        'lightgbm',
        'knn',
    ],
)
```

```
Finished loading model, total used 150 iterations
Finished loading model, total used 150 iterations
Finished loading model, total used 150 iterations
Finished loading model, total used 150 iterations
Finished loading model, total used 150 iterations
Finished loading model, total used 200 iterations
Finished loading model, total used 200 iterations
Finished loading model, total used 200 iterations

1.5.5 Backtest Multivariate Pipeline

Like univariate pipelines, multivariate pipelines can also be backtested. Info about each model and series becomes possible to compare. See the documentation.

[106]:
```
# recreate Forecaster objects to bring dates back lost from taking seasonal differences
fvol_aut = Forecaster(
    y=volume,
    current_dates=volume.index,
    future_dates=13,
)
fprice_aut = Forecaster(
    y=price,
    current_dates=price.index,
    future_dates=13,
)
```

[107]:
```
mv_backtest_results = mvpipeline.backtest(
    fvol_aut,
    fprice_aut,
    n_iter = 3,
    jump_back = 13,
    test_length = 0,
    cis = False,
    models=[
        'mlr',
        'elasticnet',
        'xgboost',
        'lightgbm',
```

Through backtesting, we can see that the multivariate approach out-performed the univariate approach. Very cool!

1.6 Scaled Automated Forecasting

- We can scale the fully automated approach to many series where we can then access all results through plotting with Jupyter widgets and export functions.
- We produce a separate forecast for avocado sales in each region in our dataset.
- This is done with a univariate approach, but cleverly using the code in this notebook, it could be transformed into a multivariate process where volume and price are forecasted together.

[109]:
```
from scalecast.notebook import results_vis
from tqdm.notebook import tqdm
```

[110]:
```
def forecaster_scaled(f,models):
    f.auto_Xvar_select(
        estimator='elasticnet',
        monitor='TestSetMAE',
        alpha=0.2,
        irr_cycles = [26],
    )
    f.tune_test_forecast(
        models,
        dynamic_testing=13,
    )
    f.set_estimator('combo')
    f.manual_forecast()
```

[111]:
```
results_dict = {}
for region in tqdm(data.region.unique()):
    series = data.loc[data['region'] == region].groupby('Date')['Total Volume'].sum()
    f_i = Forecaster(
        y = series,
```

CHAPTER

TWO

ANOMALY DETECTION

The issue with anomaly detection in time series is that an anomaly is not always well-defined. This notebook introduces several techniques native to scalecast that can be used to identify anomalies, but it is ultimately up to the user to determine what is and isn't actually an anomaly.

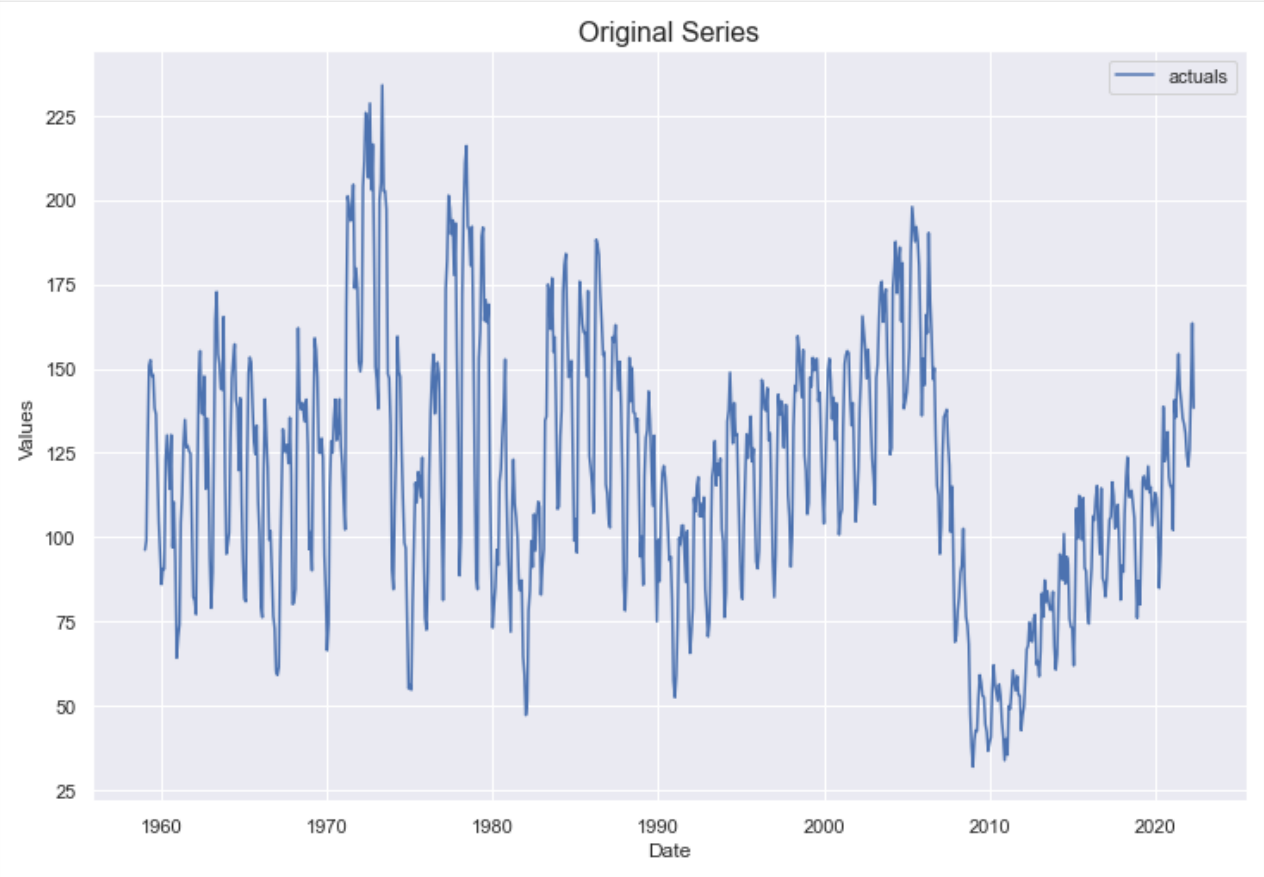
[1]:
```
import pandas as pd
import pandas_datareader as pdr
import matplotlib.pyplot as plt
import seaborn as sns
from scipy import stats
from scalecast.Forecaster import Forecaster
from scalecast.AnomalyDetector import AnomalyDetector
from scalecast.SeriesTransformer import SeriesTransformer
```

[2]:
```
sns.set(rc={'figure.figsize':(12,8)})
```

[3]:
```
df = pdr.get_data_fred(
    'HOUSTNSA',
    start='1959-01-01',
    end='2022-05-01',
).reset_index()
```

[4]:
```
f = Forecaster(
    y=df['HOUSTNSA'],
    current_dates=df['DATE']
)

f.plot()
plt.title('Original Series',size=16)
plt.show()
```

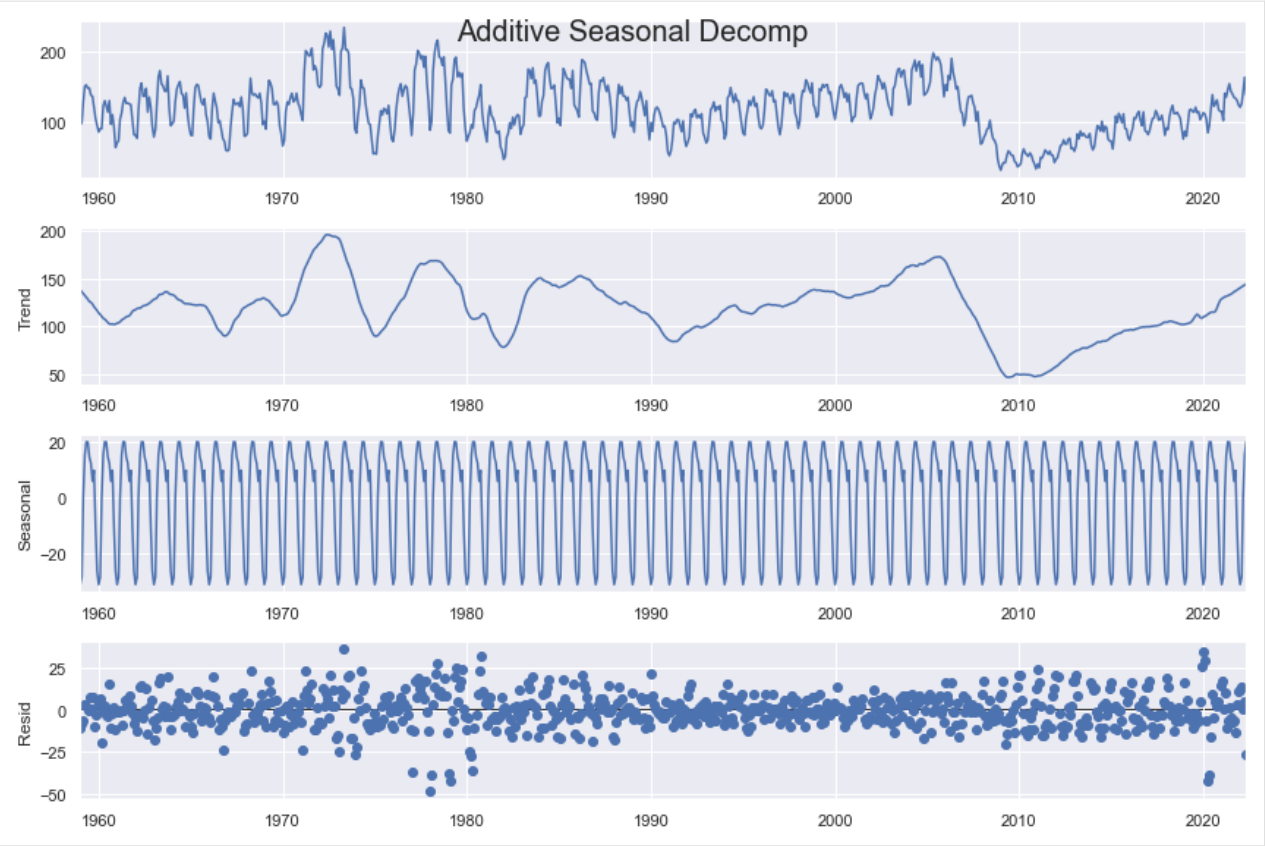


2.1 Naive Detect

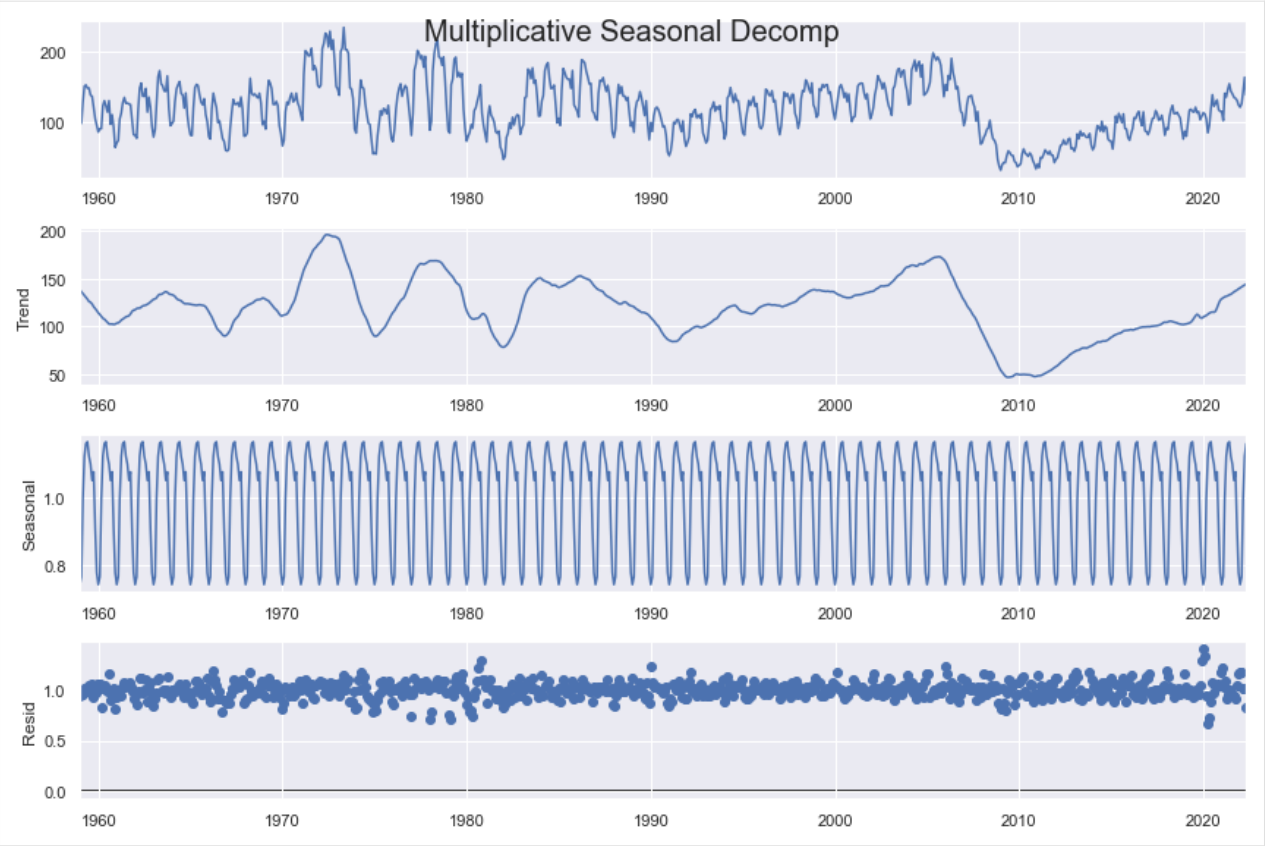
This algorithm functions by decomposing a given series into a trend, seasonal, and residual part testing the residuals' distance from the mean to identify anomalies. It is computationally cheap, but if the series isn't well-explained by the decomposition process, or the residual is not independent and/or not normal, this can be a poor way to identify anomalies.

[5]:
```
detector1 = AnomalyDetector(f)
```

[6]:
```
f.seasonal_decompose(extrapolate_trend='freq').plot()
plt.suptitle('Additive Seasonal Decomp',size=20)
plt.show()
```

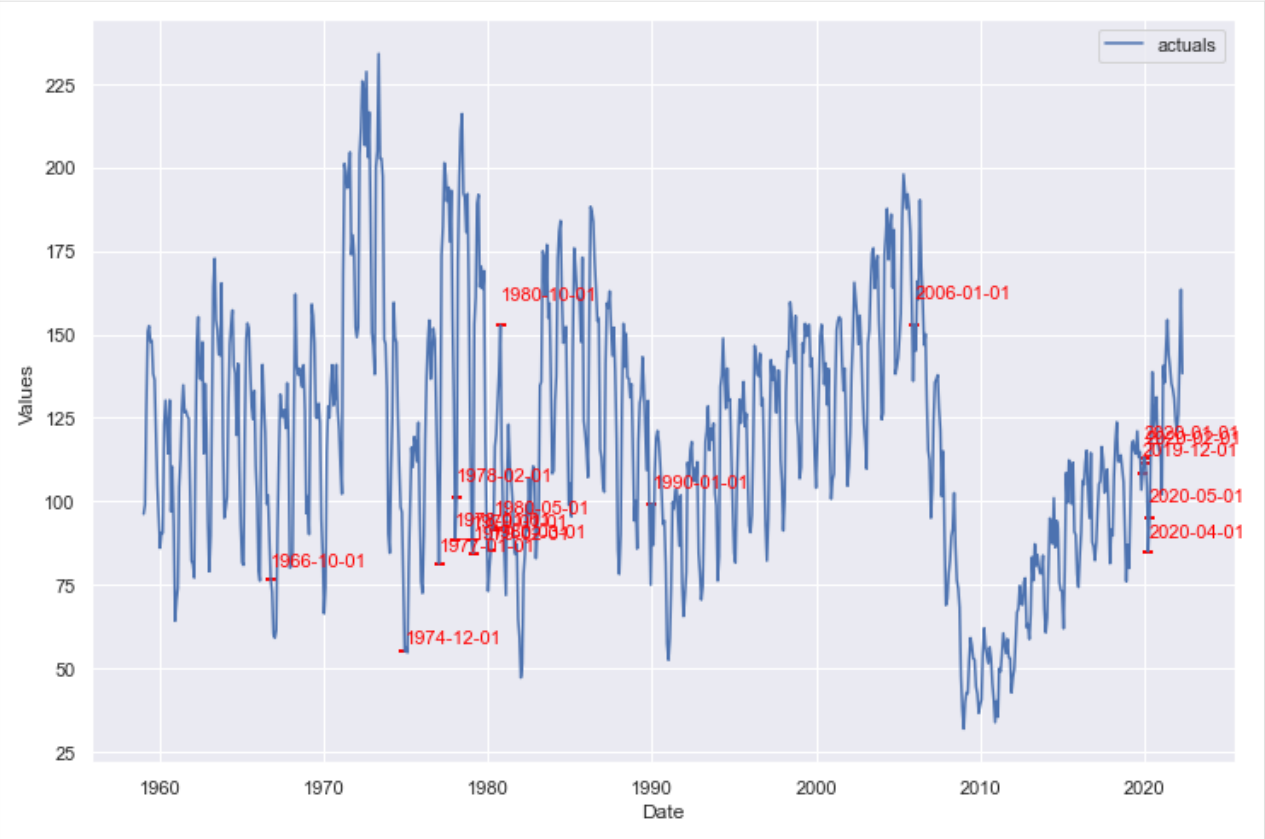


[7]:
```
f.seasonal_decompose(
    model='multiplicative',
    extrapolate_trend='freq'
).plot()
plt.suptitle('Multiplicative Seasonal Decomp',size=20)
plt.show()
```



The key parameters in the function below include the type of decomposition (additive or multiplicative), as well as the confidence level. The higher the confidence level, the fewer anomalies will be detected. The type of decomposition should conform with whichever one creates the most ideal residuals (should be normally abnd randomly distributed, independent, and homoskedastic).

[8]:
```
detector1.NaiveDetect(
    extrapolate_trend='freq',
    model='multiplicative',
    cilevel=.99,
)
detector1.plot_anom(label=True)
plt.show()
```



This method identified many anomalies and perhaps isn't the best method for this series, which exhibits irregular cycles and trends.

2.2 Monte Carlo Detect

This is a Monte Carlo simulated method that produces possible future paths for the data over some time span and uses a confidence interval to evaluate what percent of the time the actual data fell above or below the simulated paths. To make this method work properly, we should transform the distribution so that we can make it as stationary and normally distributed as possible. Therefore, extra care will be taken to prepare the data before applying the method.

To get started, we can transform the dataset so that a log transformation is taken to normalize some of the skew in the dataset, then a seasonal difference of 12 months is applied on the data, then the first difference of the resulting series is applied.

[9]:
```
f_transform = f.copy()

transformer = SeriesTransformer(f_transform)

f_transform = transformer.LogTransform()      # log transform
f_transform = transformer.DiffTransform(12)   # seasonally adjust
f_transform = transformer.DiffTransform(1)    # first difference

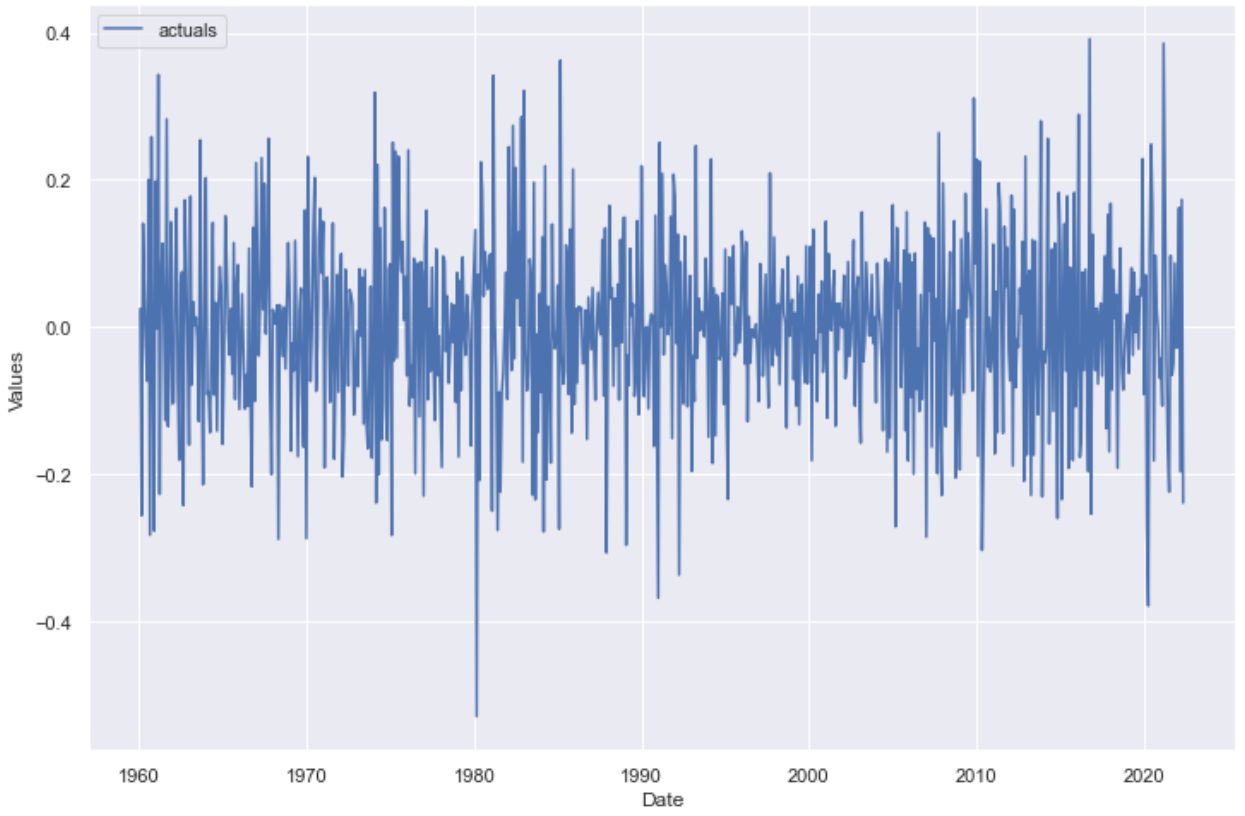
detector2 = AnomalyDetector(f_transform)
```

All of these transformations, as well as any models run after the transformations were called, are revertible by calling their reversion counterpart methods in revserse order, demonstrated (by not applied) by the code below:

```
# how to revert all transformations
f_transform = transformer.DiffRevert(1)
f_transform = transformer.DiffRevert(12)
f_transform = transformer.LogRevert()
```

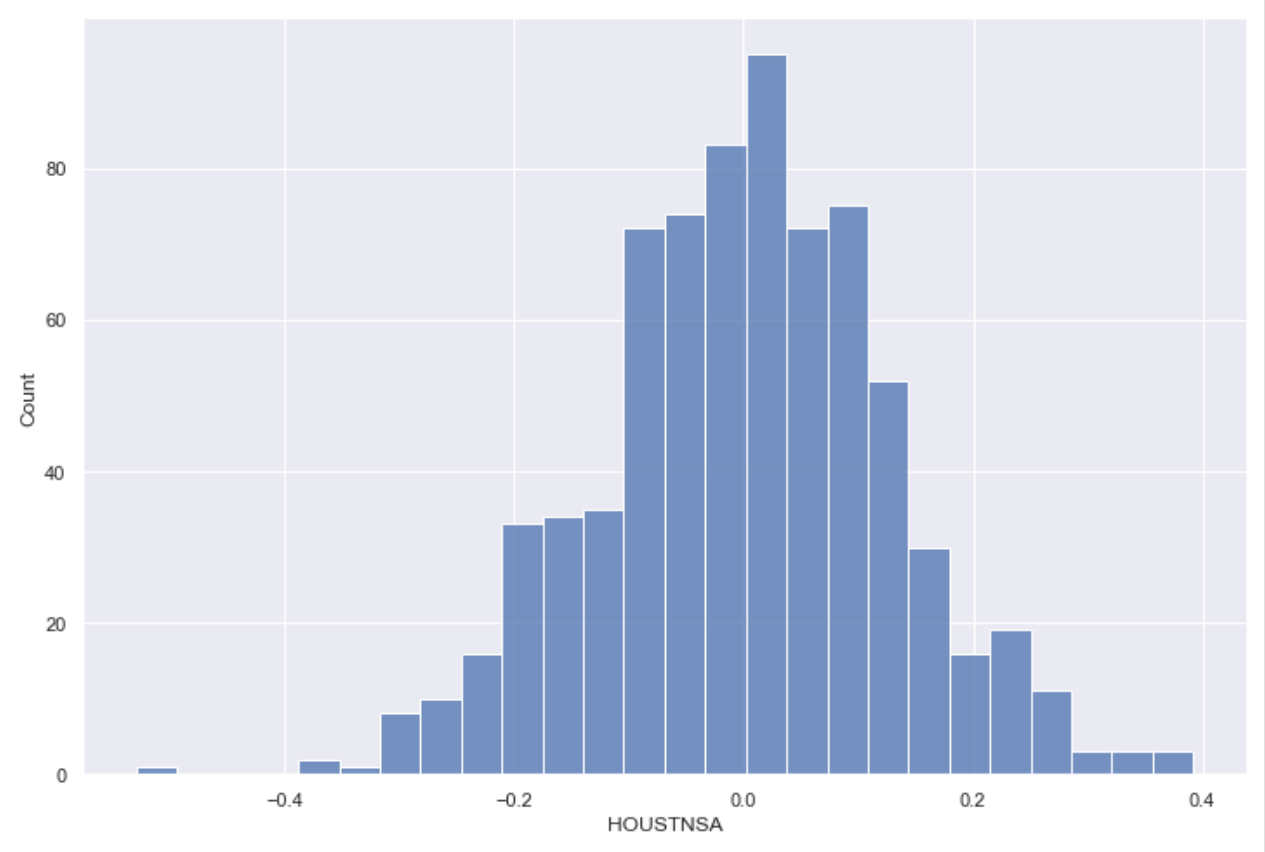
Now, we can see the resulting series:

[10]:
```
f_transform.plot()
plt.show()
```



Call a histogram to make sure it looks normal:

[11]:
```
sns.histplot(f_transform.y)
plt.show()
```



Call a statistical test to ensure its normality:

[12]:
```
critical_pval = 0.05
print('-'*100)
k2, p = stats.normaltest(f_transform.y.values)
print("D'Agostino and Pearson's test result for normality:")
print('the test-stat value is: {:.2f}'.format(k2))
print('the p-value is {:.4f}'.format(p))
print('the series is {}'.format('not normal' if p < critical_pval else 'normal'))
print('-'*100)
```

```
----------------------------------------------------------------------------------------------------
↪-----------
D'Agostino and Pearson's test result for normality:
the test-stat value is: 4.55
the p-value is 0.1028
the series is normal
----------------------------------------------------------------------------------------------------
↪-----------
```

Call a statistical test to ensure its stationarity:

[13]:
```
print('-'*100)
print('Augmented Dickey-Fuller results:')
stat, pval, _, _, _, _ = f_transform.adf_test(full_res=True,maxlag=12)
print('the test-stat value is: {:.2f}'.format(stat))
```

(continues on next page)

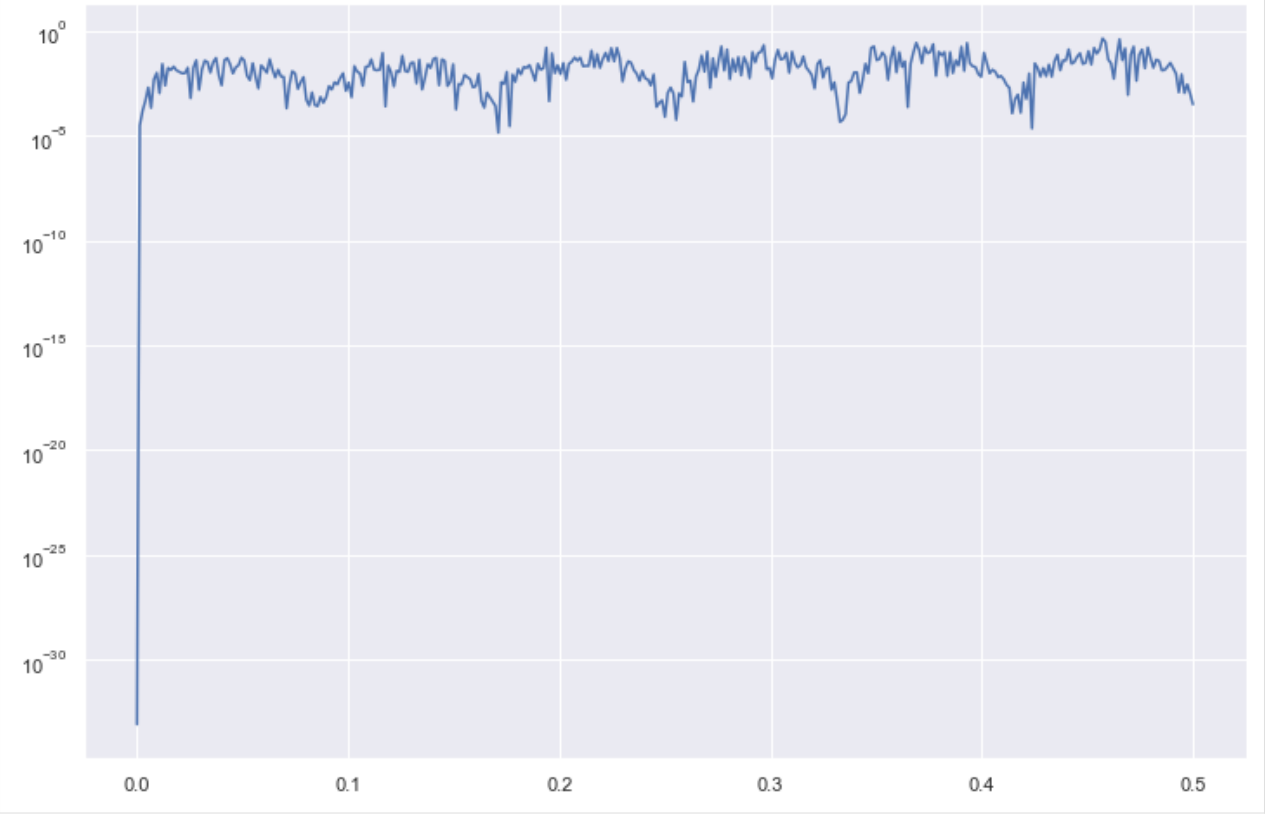
(continued from previous page)

```
print('the p-value is {:.4f}'.format(pval))
print('the series is {}'.format('stationary' if pval < critical_pval else 'not stationary
↪'))
print('-'*100)
```

```
----------------------------------------------------------------------------------------------------
↪-----------
Augmented Dickey-Fuller results:
the test-stat value is: -11.72
the p-value is 0.0000
the series is stationary
----------------------------------------------------------------------------------------------------
↪-----------
```

Now, we can check out its periodogram to make sure no further adjustments are needed to the data:

[14]:
```
a, b = f_transform.plot_periodogram()
plt.semilogy(a, b)
plt.show()
```



This shows that there may be some cycles within the data that show stronger effects than other cycles, but for the most part, the periodogram is pretty stable. We can say that the transformations we took work for our purposes.

Now we can call the method and plot the results:

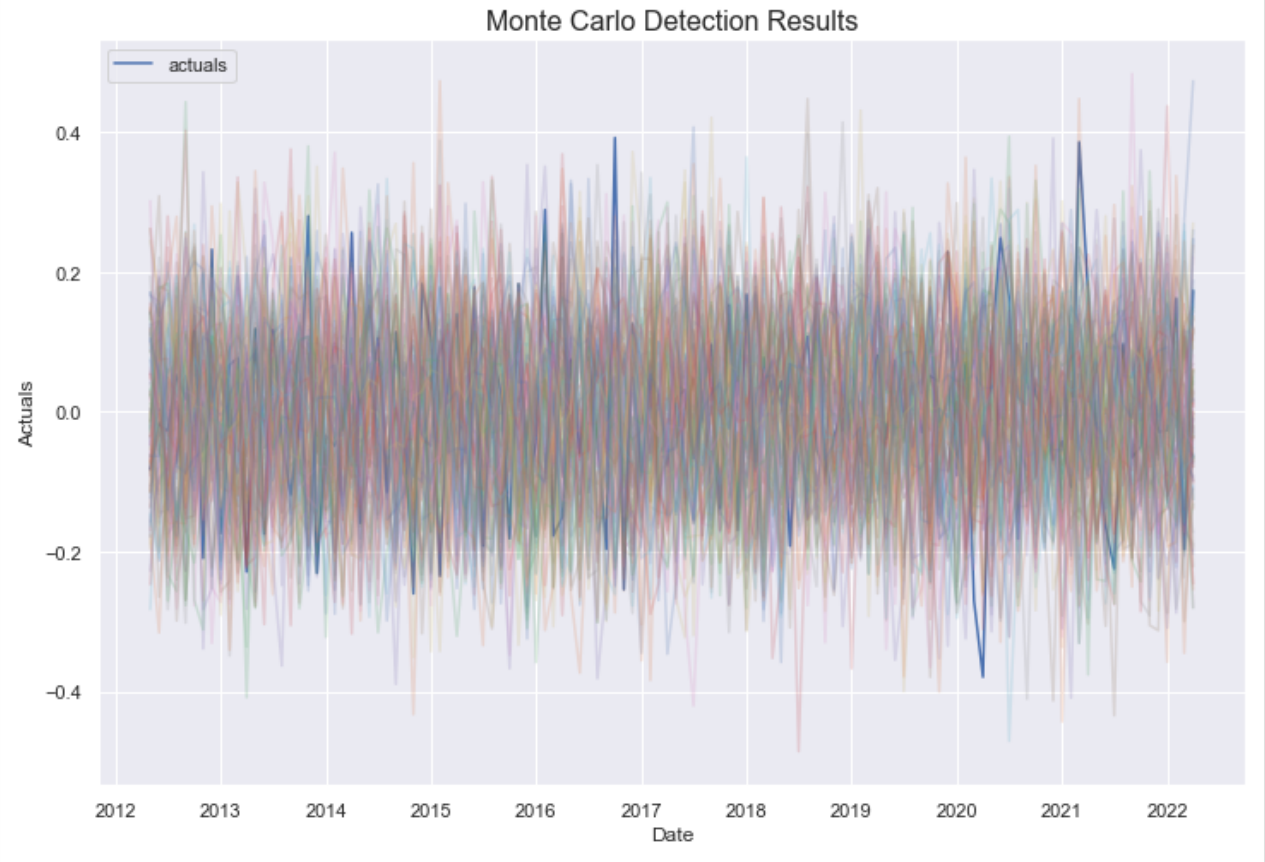
[15]:
```
detector2.MonteCarloDetect(
    start_at = '2012-05-01',
```

(continues on next page)

(continued from previous page)

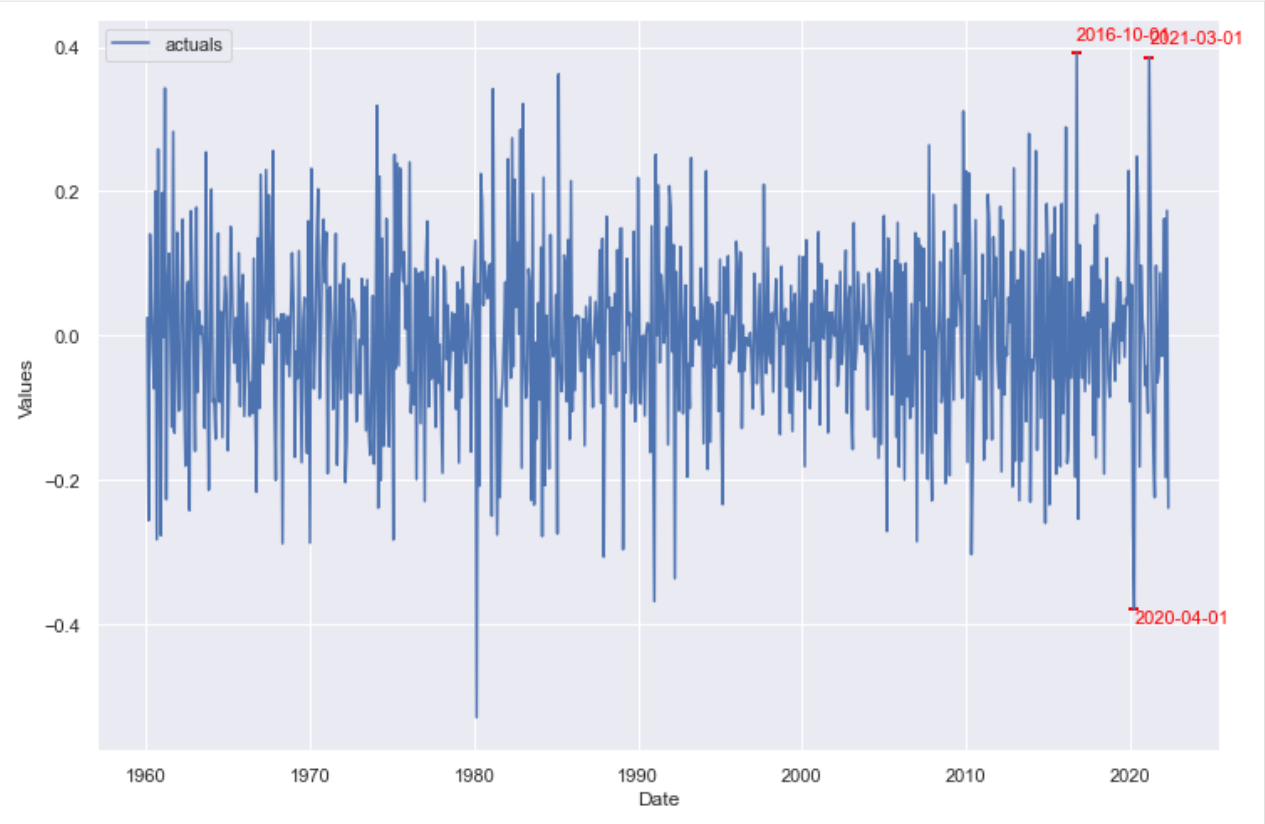
```
    stop_at = '2022-05-01',
    cilevel=.99,
)

detector2.plot_mc_results()
plt.title('Monte Carlo Detection Results',size=16)
plt.show()
```



The blue line is the series' actual values and the colored lines are the results of each of 100 monte carlo simulations applied on the last 10 years of data available in the set. The few points that clearly stick above or below all colored lines will most likely be labeled as anomalies.

[16]:
```
detector2.plot_anom()
plt.show()
```



We see three points identified: - Oct. 2016
- April 2020 (first month of the COVID pandemic)
- March 2021

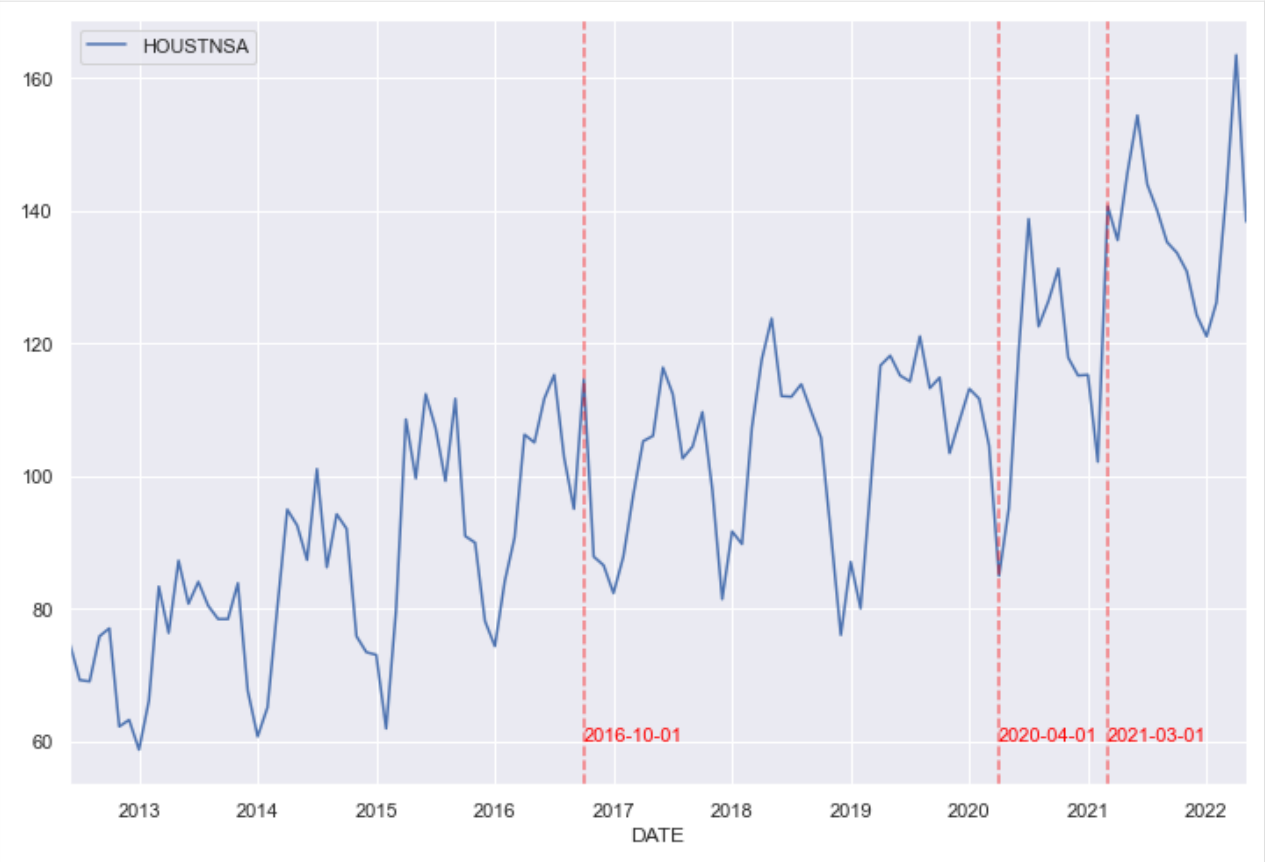
We can plot those points back onto our original series:

[17]:
```
_, ax = plt.subplots()

df.iloc[-120:,:].plot(x='DATE',y='HOUSTNSA',ax=ax)

for i,v in zip(detector2.labeled_anom.index,detector2.labeled_anom):
    if v == 1:
        ax.axvline(i,linestyle='--',color='red',alpha=.5)
        ax.text(
            i+pd.Timedelta(days=2),
            60,
            s=i.strftime('%Y-%m-%d'),
            color='red',
            size=11
        )

plt.show()
```



Let's dig into these three points a little more closely.

[18]:
```
df2 = df.copy()
df2['year'] = df2.reset_index().DATE.dt.year
df2['month'] = df2.reset_index().DATE.dt.month
df2['pct_chg'] = df2['HOUSTNSA'].pct_change()
```

[19]:
```
avg_chg_month = df2.groupby('month')['pct_chg'].mean().reset_index()
avg_chg_month['pct_chg_std'] = df2.groupby('month')['pct_chg'].std().values
avg_chg_month['pct_chg_2016'] = df2.loc[df2['year'] == 2016,'pct_chg'].values
avg_chg_month['pct_chg_2020'] = df2.loc[df2['year'] == 2020,'pct_chg'].values
avg_chg_month['pct_chg_2021'] = df2.loc[df2['year'] == 2021,'pct_chg'].values

def highlight_rows(row):

    lightgreen = 'background-color: lightgreen;'
    highlight = 'background-color: lightcoral;'
    default = ''

    if row['month'] == 3:
        return [default,lightgreen,lightgreen,default,default,highlight]
    elif row['month'] == 4:
        return [default,lightgreen,lightgreen,default,highlight,default]
    elif row['month'] == 10:
        return [default,lightgreen,lightgreen,highlight,default,default]
```

(continues on next page)

(continued from previous page)

```
    else:
        return [default,lightgreen,lightgreen,default,default,default]

avg_chg_month.style.apply(
    highlight_rows,
    axis=1
).format(
    {var:'{:.1%}'.format for var in avg_chg_month.iloc[:,1:]}
)
```

[19]:
```
<pandas.io.formats.style.Styler at 0x1606589d4c0>
```

The reason October 2016 was identified was due to how much more it increased in value from the previous month compared to Octobers from other years. The April 2020 point, as is logical, is from a precipitous decrease in housing starts after the COVID-19 pandemic began. The March 2021 point is the hardest to logically explain, but could be from a large year-over-year increase–a stronger than expected recovery from COVID.

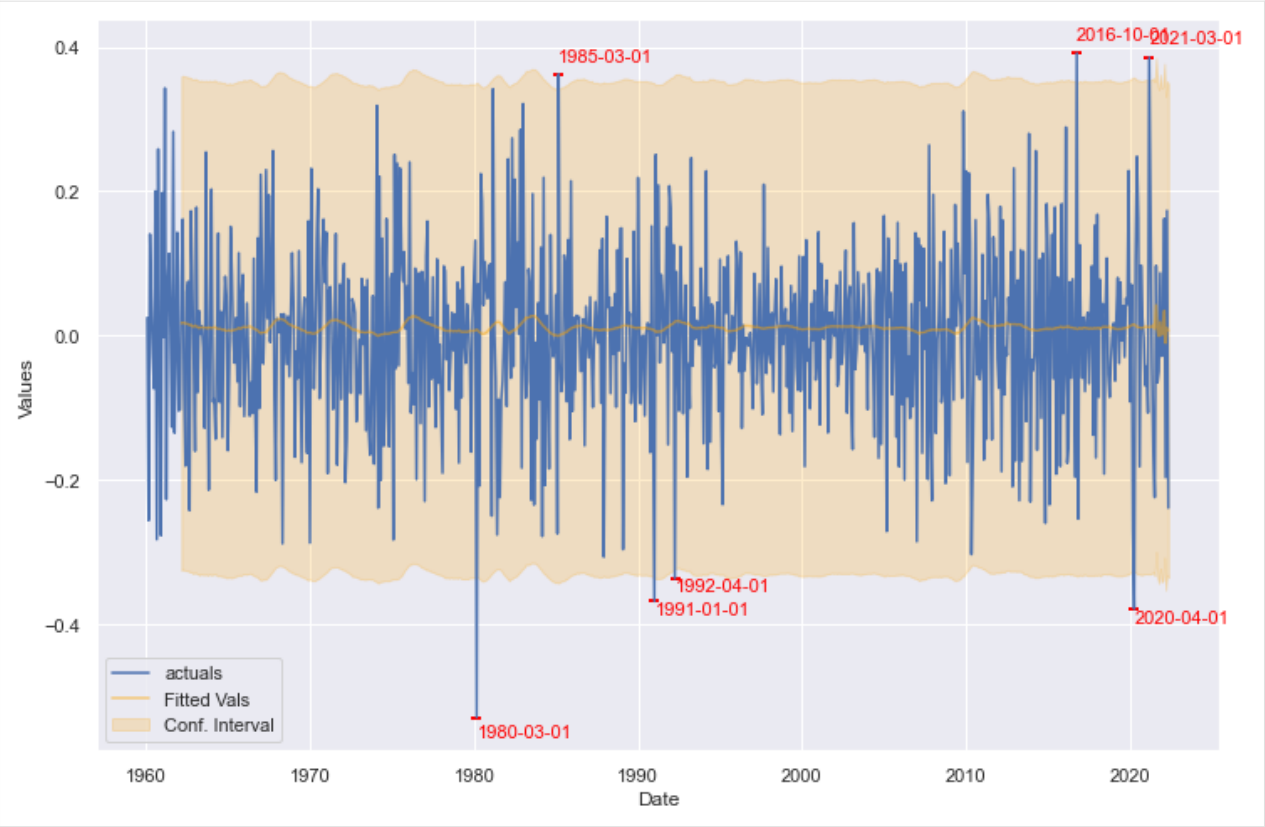
2.3 LSTM Detect

Another technique to identify anomalies includes using an estimator native to scalecast to create bootstrapped confidence intervals around fitted values. All actual values that fall outside of the generated confidence intervals are considered anomalies. This concept is very simple to understand. Let's see how the LSTM model performs in such a process on the same transformed series we used in the Monte Carlo detect.

[18]:
```
detector3 = AnomalyDetector(f_transform)
```

[19]:
```
detector3.EstimatorDetect(
    estimator='lstm',
    future_dates=12, # how many forecast steps to train into the lstm? default is 1
    cilevel=.99,
    lags=24,
    epochs=10,
    lstm_layer_sizes=(64,64,64),
    dropout=(0,0,0),
    verbose=0,
)
```

[20]:
```
detector3.plot_anom()
plt.show()
```



The LSTM model does not create a tight fit for this series, but it knows its performance is bad and creates large confidence intervals. As such, we see the same three points identified from the Monte Carlo technique, as well as an additional four points identified from early parts in the series' history. Due to the random nature of this model, results may vary each time it is run.

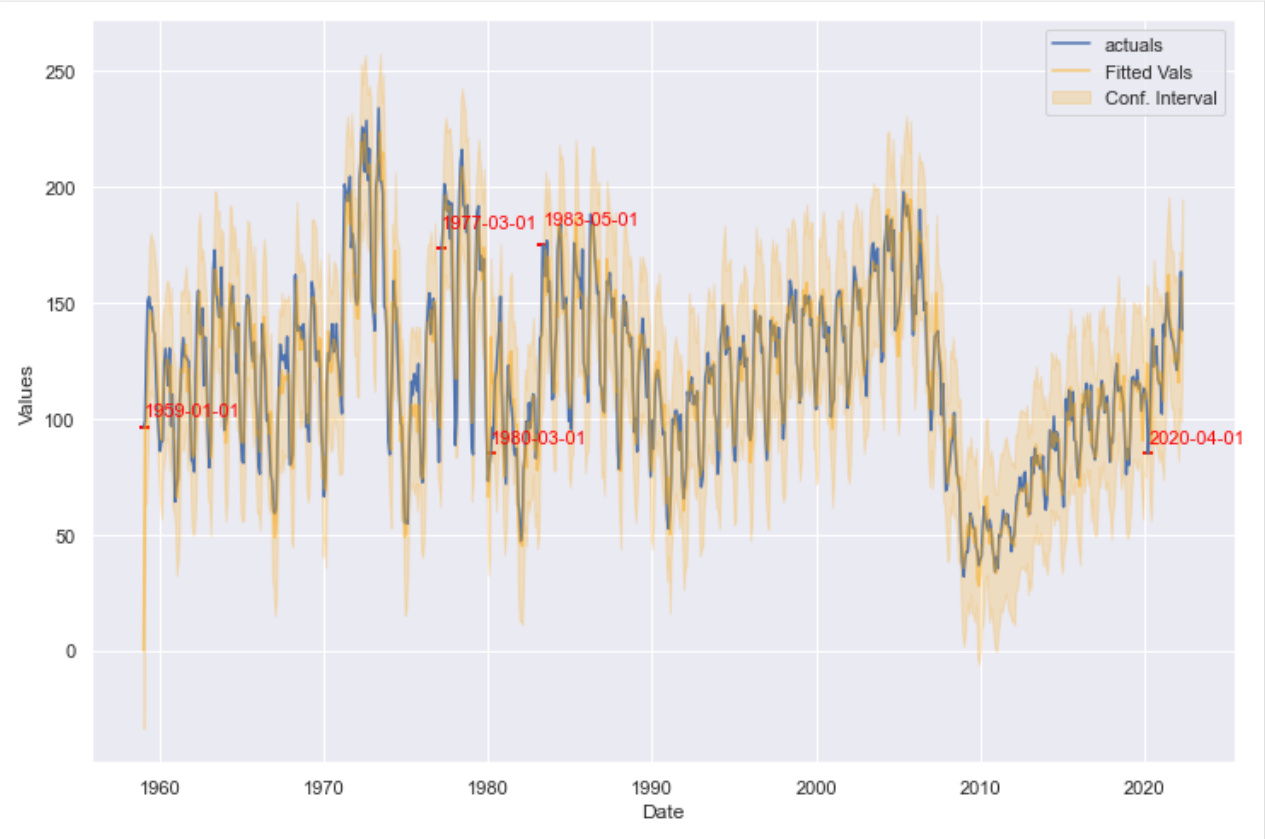
2.4 ARIMA Detect

Finally, we use the same technique as described above, but change the underlying estimator to ARIMA. We apply the model on the non-transformed series and see the results.

[21]:
```
detector4 = AnomalyDetector(f)
```

[22]:
```
detector4.EstimatorDetect(
    estimator='arima',
    cilevel=.99,
    order=(2,1,2),
    seasonal_order=(2,0,0,12),
)
```

[23]:
```
detector4.plot_anom()
plt.show()
```



The ARIMA model creates a much tighter fit than the LSTM model, but creates tighter confidence intervals as well. According to this method, October 2016 and March 2021 are no longer anomalies, but April 2020 remains. It also identifies several points earlier in the series' history.

CHAPTER

THREE

ARIMA

An introduction to ARIMA forecasting with scalecast.

- data: https://www.kaggle.com/datasets/rakannimer/air-passengers
- blog post: https://towardsdatascience.com/forecast-with-arima-in-python-more-easily-with-scalecast-35125fc7dc2e

[1]:
```
import pandas as pd
import numpy as np
from scalecast.Forecaster import Forecaster
from scalecast.auxmodels import auto_arima
import matplotlib.pyplot as plt
import seaborn as sns
import warnings
```

[2]:
```
df = pd.read_csv('AirPassengers.csv')
f = Forecaster(
    y=df['#Passengers'],
    current_dates=df['Month'],
    future_dates = 12,
    test_length = .2,
    cis = True,
)
f
```

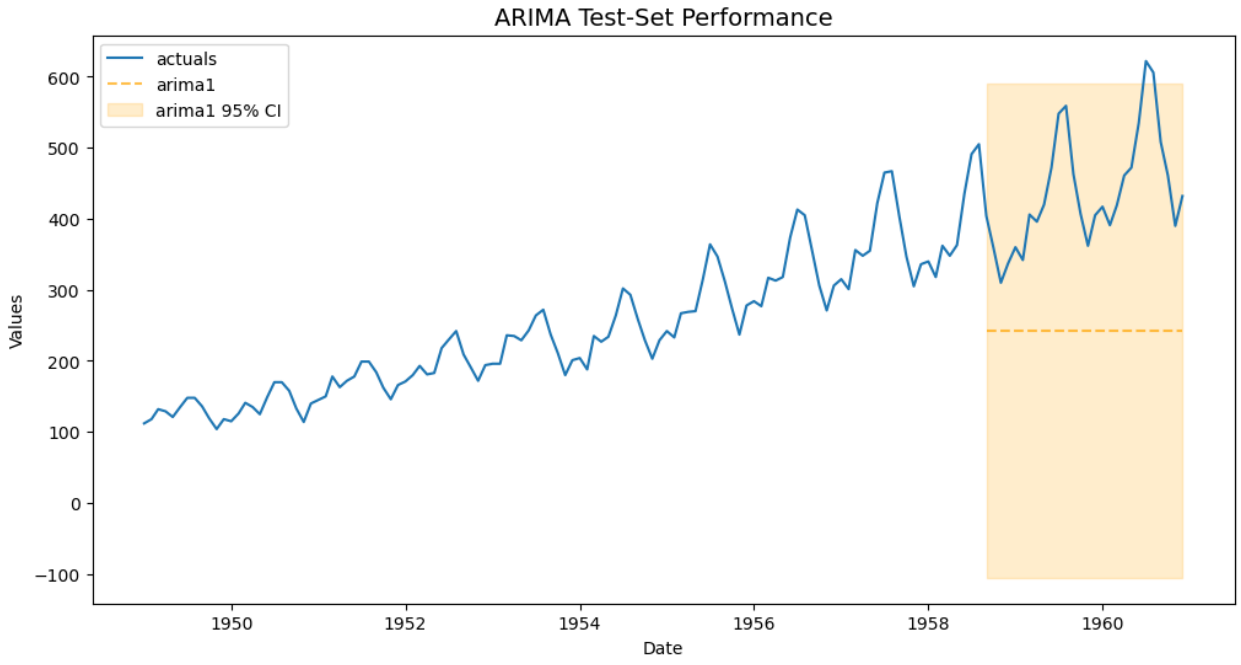
[2]:
```
Forecaster(
    DateStartActuals=1949-01-01T00:00:00.000000000
    DateEndActuals=1960-12-01T00:00:00.000000000
    Freq=MS
    N_actuals=144
    ForecastLength=12
    Xvars=[]
    TestLength=28
    ValidationMetric=rmse
    ForecastsEvaluated=[]
    CILevel=0.95
    CurrentEstimator=mlr
    GridsFile=Grids
)
```

3.1 Naive Simple Approach

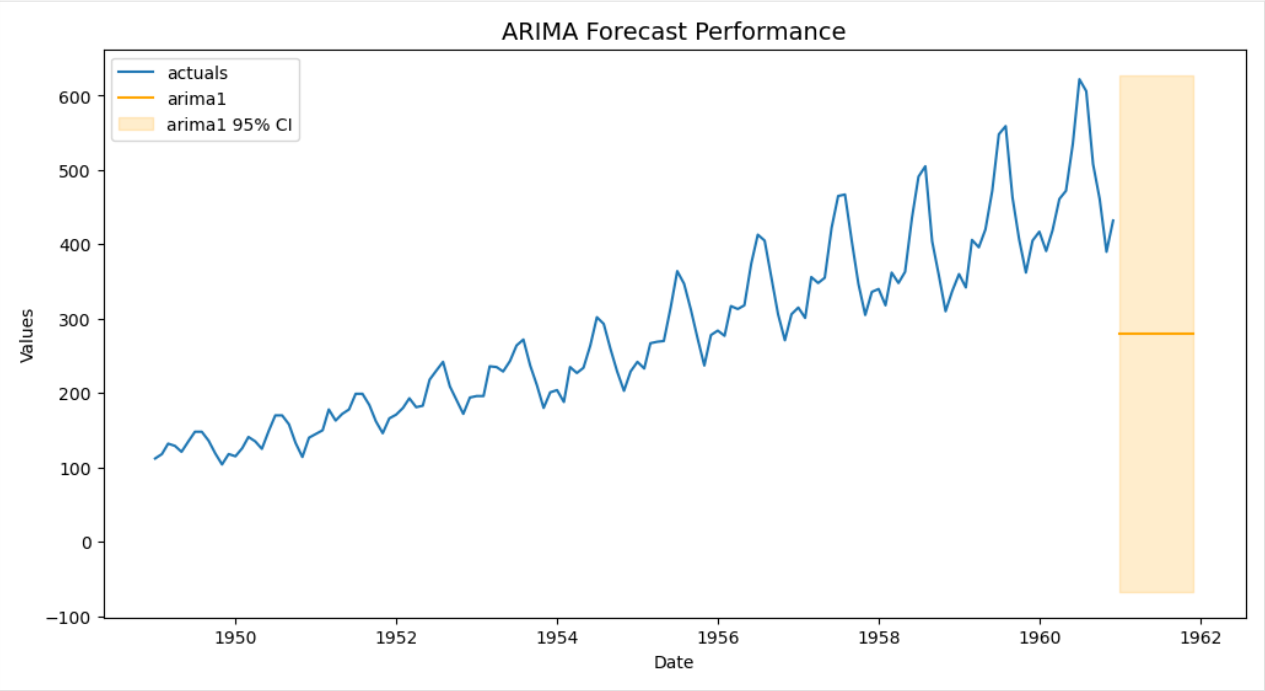
- this is not meant to be a demonstration of a model that is expected to be accurate
- it is meant to show the mechanics of using scalecast

[3]:
```
f.set_estimator('arima')
f.manual_forecast(call_me='arima1')
```

[4]:
```
f.plot_test_set(ci=True)
plt.title('ARIMA Test-Set Performance',size=14)
plt.show()
```



[5]:
```
f.plot(ci=True)
plt.title('ARIMA Forecast Performance',size=14)
plt.show()
```

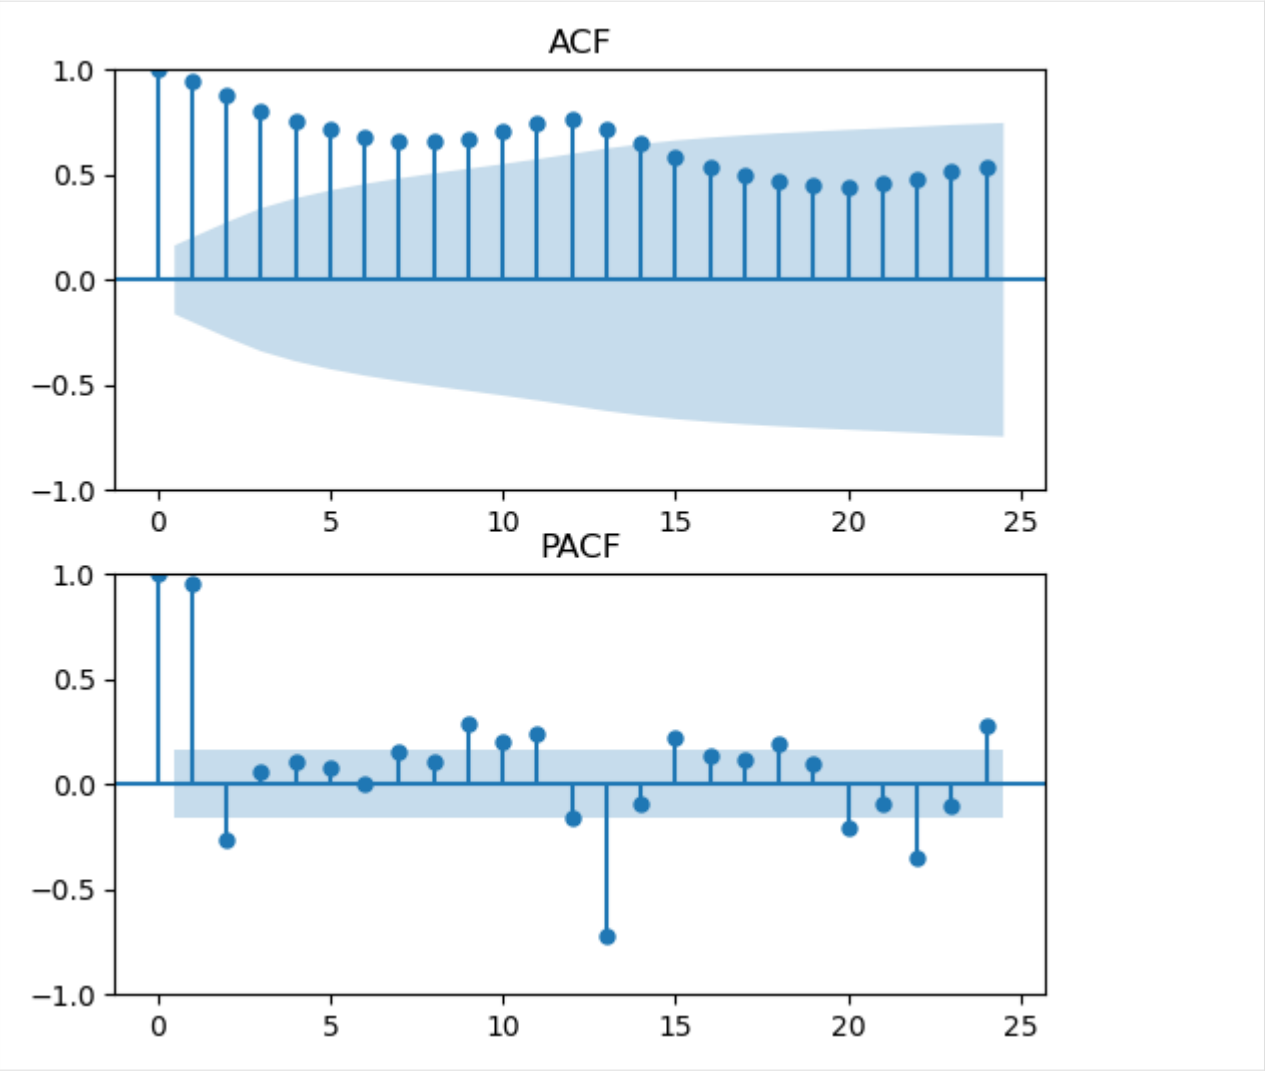


3.2 Human Interpretation Iterative Approach

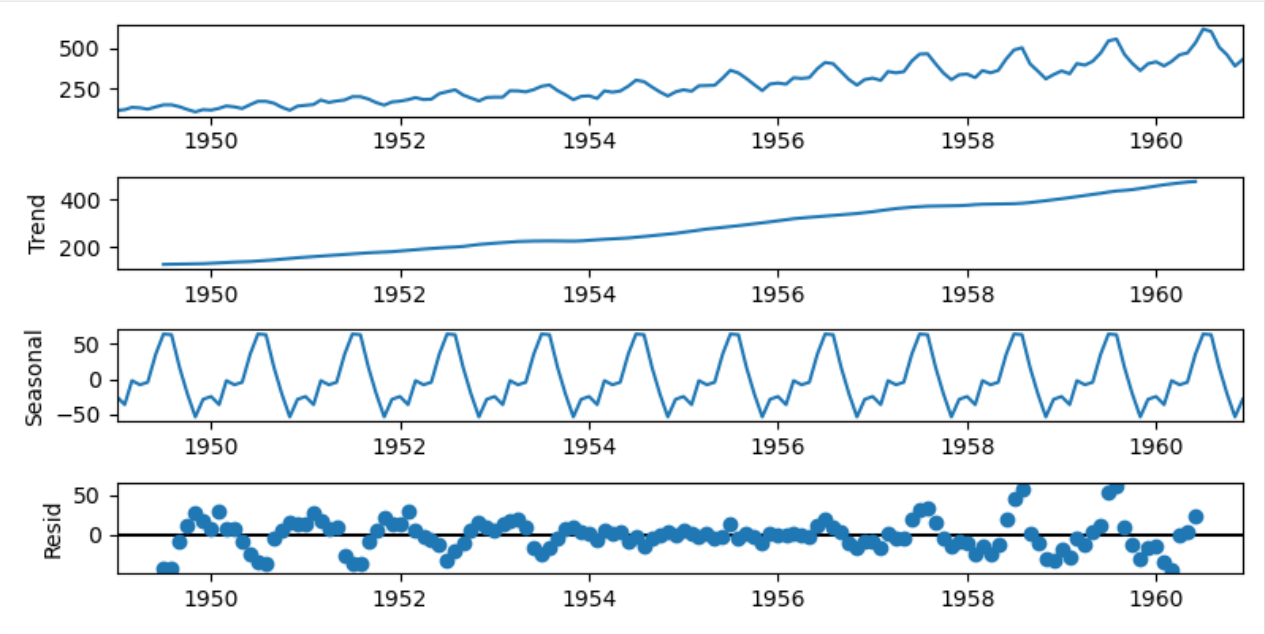
- this is a non-automated approach to ARIMA forecasting where model specification depends on human-interpretation of statistical results and charts

[6]:
```
figs, axs = plt.subplots(2, 1,figsize=(6,6))
f.plot_acf(ax=axs[0],title='ACF',lags=24)
f.plot_pacf(ax=axs[1],title='PACF',lags=24)
plt.show()
```

```
/Users/uger7/opt/anaconda3/envs/scalecast-env/lib/python3.8/site-packages/statsmodels/
↪graphics/tsaplots.py:348: FutureWarning: The default method 'yw' can produce PACF␣
↪values outside of the [-1,1] interval. After 0.13, the default will change␣
↪tounadjusted Yule-Walker ('ywm'). You can use this method now by setting method='ywm'.
  warnings.warn(
```



[7]:
```
plt.rc("figure",figsize=(8,4))
f.seasonal_decompose().plot()
plt.show()
```

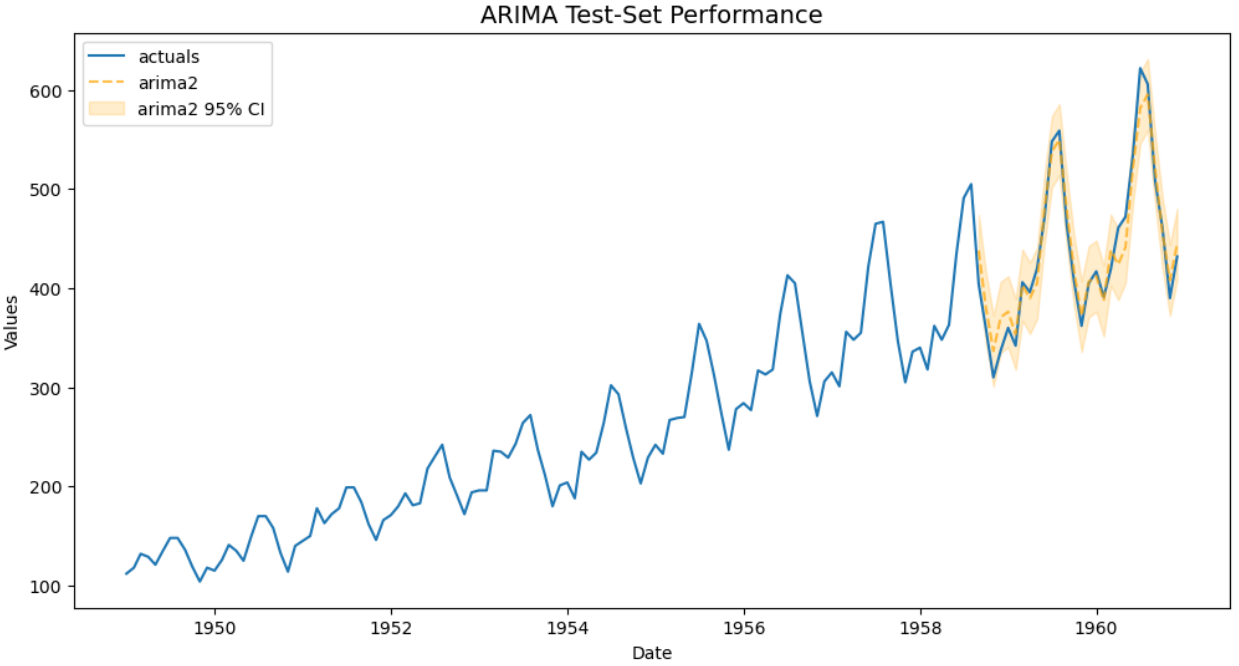


[8]:
```
stat, pval, _, _, _, _ = f.adf_test(full_res=True)
print(stat)
print(pval)
```

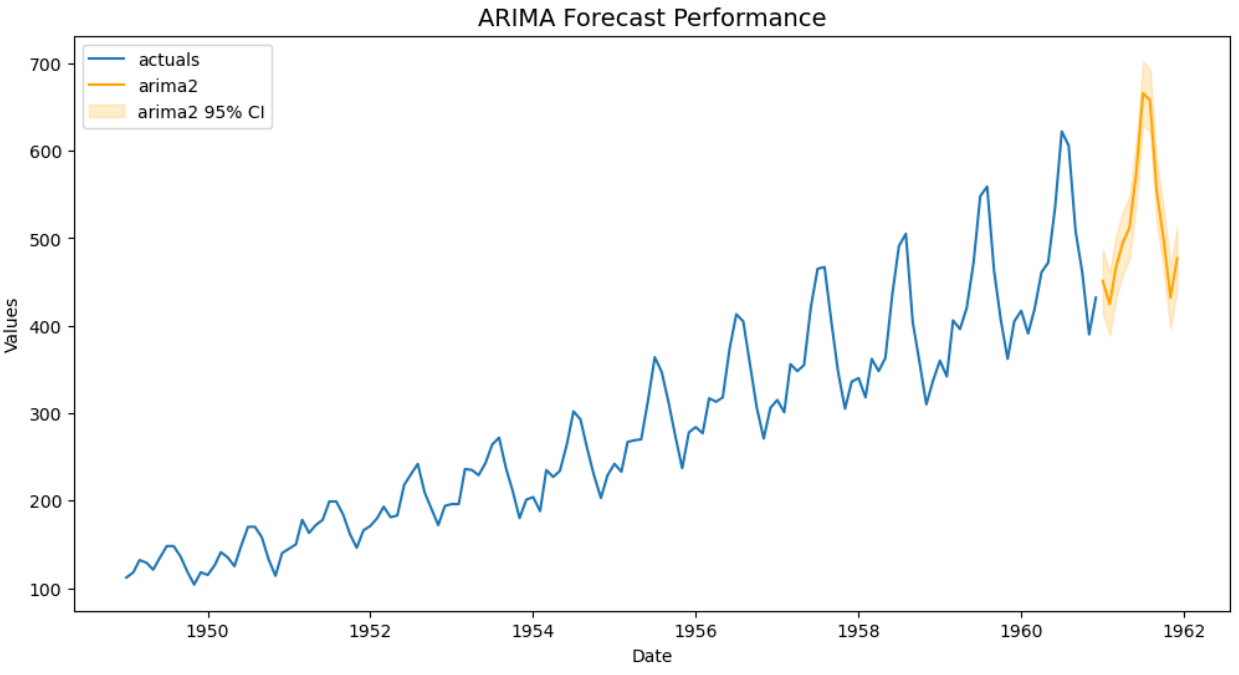
```
0.8153688792060442
0.9918802434376409
```

[9]:
```
f.manual_forecast(order=(1,1,1),seasonal_order=(2,1,1,12),call_me='arima2')
```

[10]:
```
f.plot_test_set(ci=True,models='arima2')
plt.title('ARIMA Test-Set Performance',size=14)
plt.show()
```



[11]:
```
f.plot(ci=True,models='arima2')
plt.title('ARIMA Forecast Performance',size=14)
plt.show()
```



[12]:
```
f.regr.summary()
```

[12]:
```
<class 'statsmodels.iolib.summary.Summary'>
"""
```

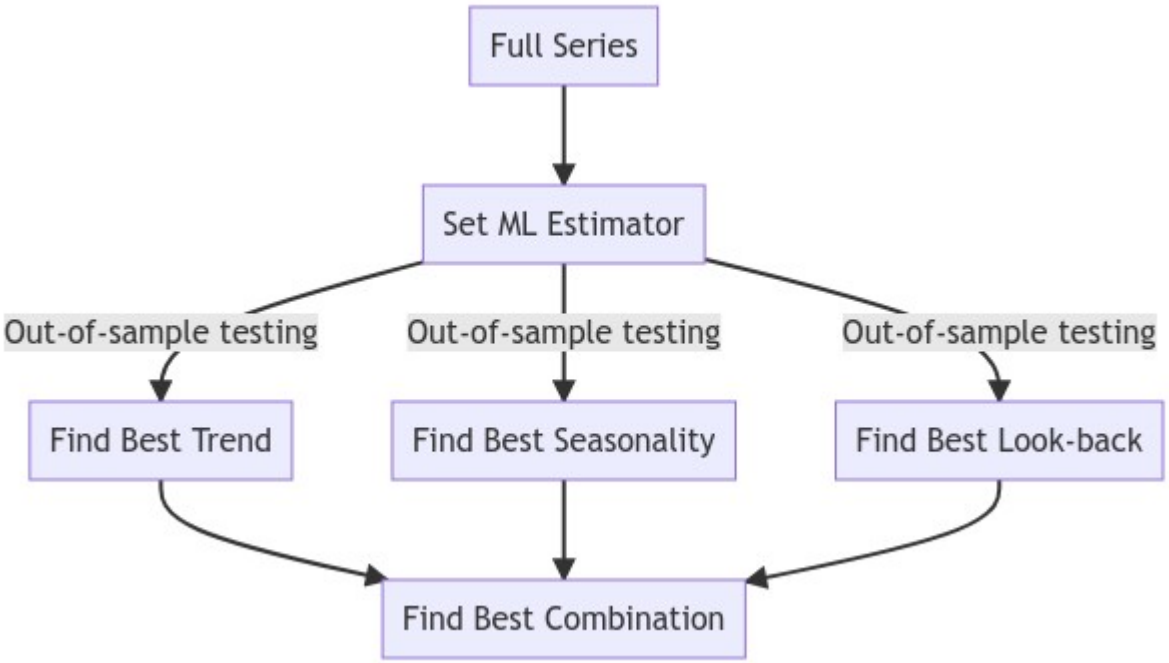
FOUR

AUTO FEATURE SELECTION

- What model combinations can be used to find the ideal features to model a time series with and also to make the best forecasts?
- See Auto Model Specification with ML Techniques for Time Series

[1]:
```
import pandas as pd
import numpy as np
from scalecast.Forecaster import Forecaster
from scalecast.util import metrics
import matplotlib.pyplot as plt
import seaborn as sns
from tqdm.notebook import tqdm
```

Diagram to demonstrate the auto_Xvar_select() method:



4.1 Use 50 Random Series from M4 Hourly

[2]:
```
models = (
    'mlr',
    'elasticnet',
    'gbt',
    'knn',
    'svr',
    'mlp',
)

Hourly = pd.read_csv(
    'Hourly-train.csv',
    index_col=0,
).sample(50)

Hourly_test = pd.read_csv(
    'Hourly-test.csv',
    index_col=0,
)
Hourly_test = Hourly_test.loc[Hourly.index]

info = pd.read_csv(
    'M4-info.csv',
    index_col=0,
    parse_dates=['StartingDate'],
    dayfirst=True,
)

results = pd.DataFrame(
    index = models,
    columns = models,
).fillna(0)
```

4.2 Run all Model Combos and Evaluate SMAPE

[3]:
```
for i in tqdm(Hourly.index):
    y = Hourly.loc[i].dropna()
    sd = info.loc[i,'StartingDate']
    fcst_horizon = info.loc[i,'Horizon']
    cd = pd.date_range(
        start = sd,
        freq = 'H',
        periods = len(y),
    )
    f = Forecaster(
        y = y,
        current_dates = cd,
        future_dates = fcst_horizon,
        test_length = fcst_horizon, # for finding xvars
```

(continues on next page)

CHAPTER

FIVE

BACKTESTED DYNAMIC CONFIDENCE INTERVALS

This notebook demonstrates how to create an expanding confidence interval using conformal intervals and backtesting. It expands what is demonstrated in the Confidence Intervals Notebook. Requires `scalecast>=0.18.1`.

We overwrite the static naive intervals produced by scalecast by default with dynamic expanding intervals obtained from backtesting.

See the article.

[1]:
```
import pandas as pd
import numpy as np
from scalecast.Forecaster import Forecaster
from scalecast.util import (
    metrics,
    backtest_metrics,
    backtest_for_resid_matrix,
    get_backtest_resid_matrix,
    overwrite_forecast_intervals,
)
from scalecast.Pipeline import Pipeline, Transformer, Reverter
import pandas_datareader as pdr
import matplotlib.pyplot as plt
import seaborn as sns
import time
```

[2]:
```
val_len = 24
fcst_len = 24
```

- Link to data: https://fred.stlouisfed.org/series/HOUSTNSA

[3]:
```
housing = pdr.get_data_fred('HOUSTNSA',start='1900-01-01',end='2021-06-01')
housing.head()
```

[3]:
```
            HOUSTNSA
DATE
1959-01-01      96.2
1959-02-01      99.0
1959-03-01     127.7
1959-04-01     150.8
1959-05-01     152.5
```

Hold out a test set since scalecast uses its native test set to determine interval widths, therefore overfitting the interval to the test set.

[4]:
```
starts_sep = housing.iloc[-fcst_len:,0]
starts = housing.iloc[:-fcst_len,0]
```

[5]:
```
f = Forecaster(
    y=starts,
    current_dates=starts.index,
    future_dates=fcst_len,
    test_length=val_len,
    validation_length=val_len,
    cis=True,
)
```

5.1 Step 1: Build and fit_predict() Pipeline

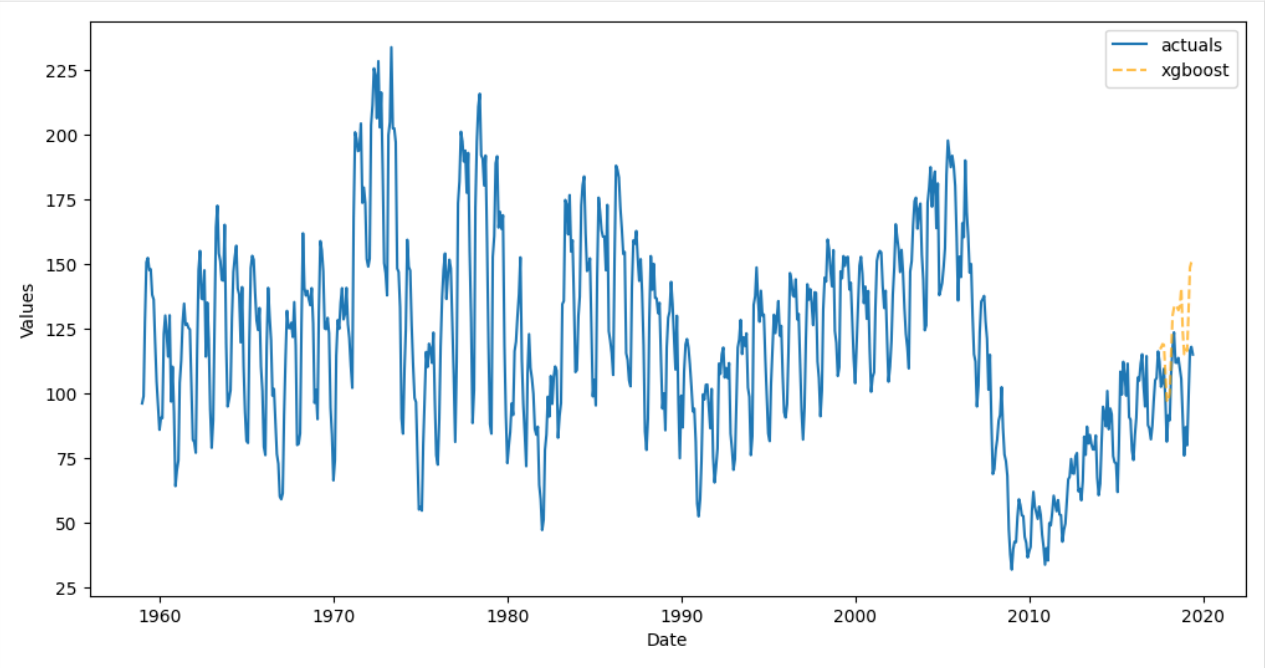
[6]:
```
transformer = Transformer(['DiffTransform'])
reverter = Reverter(['DiffRevert'],transformer)
```

[7]:
```
def forecaster(f):
    f.add_ar_terms(100)
    f.add_seasonal_regressors('month')
    f.set_estimator('xgboost')
    f.manual_forecast()
```

[8]:
```
pipeline = Pipeline(
    steps = [
        ('Transform',transformer),
        ('Forecast',forecaster),
        ('Revert',reverter)
    ]
)
```

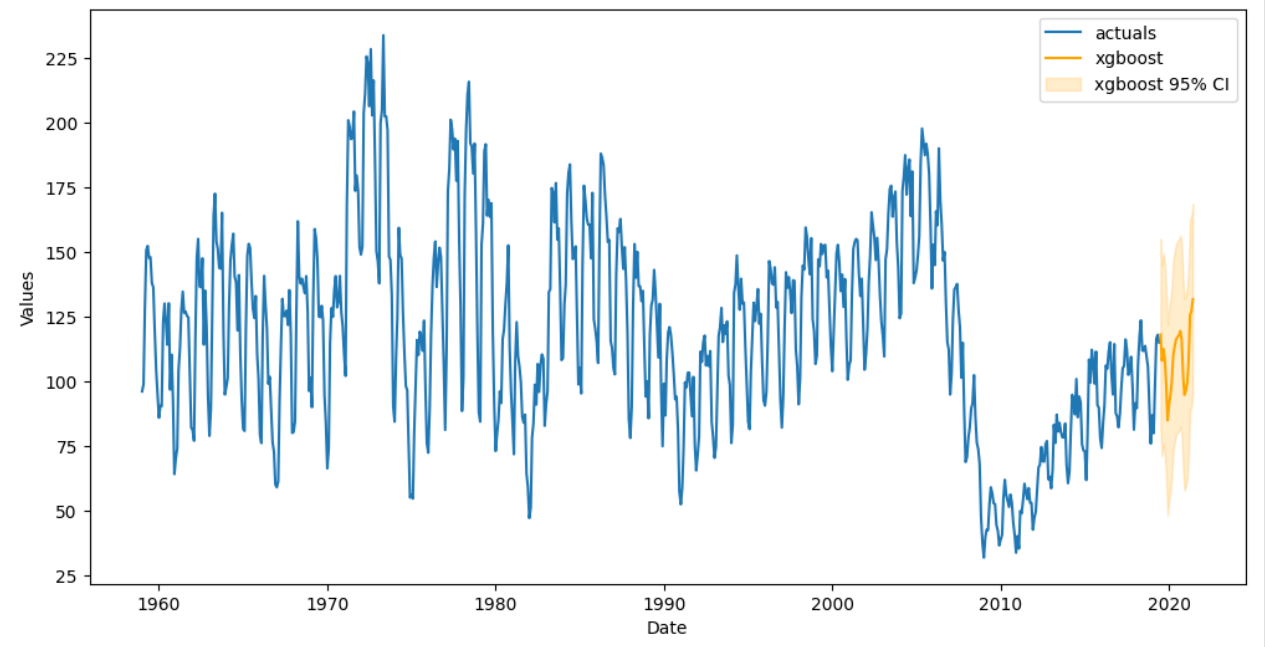
[9]:
```
f = pipeline.fit_predict(f)
```

[10]:
```
f.plot_test_set();
```



5.1.1 Score the default Interval

[11]:
```
f.plot(ci=True);
```

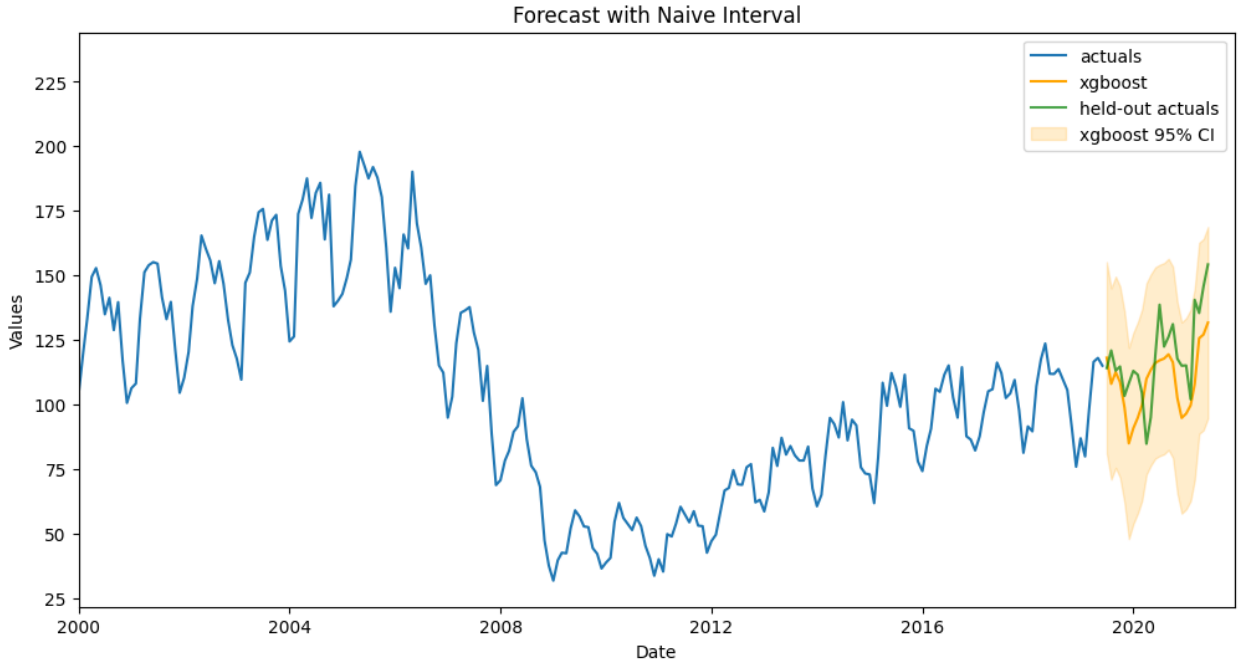


[12]:
```
fig, ax = plt.subplots(figsize=(12,6))
f.plot(ci=True,models='top_1',order_by='TestSetRMSE',ax=ax)
sns.lineplot(
    y = 'HOUSTNSA',
```

(continues on next page)

(continued from previous page)

```
    x = 'DATE',
    data = starts_sep.reset_index(),
    ax = ax,
    label = 'held-out actuals',
    color = 'green',
    alpha = 0.7,
)
plt.xlim(pd.Timestamp('2000-01-01'),pd.Timestamp('2021-12-01'))
plt.title('Forecast with Naive Interval')
plt.show()
```



[13]:
```
print(
    'All confidence intervals for every step'
    ' are {:.2f} units away from the point predictions.'.format(
        f.history['xgboost']['UpperCI'][0] - f.history['xgboost']['Forecast'][0]
    )
)
print(
    'The interval contains {:.2%} of the actual values'.format(
        np.sum(
            [
                1 if a <= uf and a >= lf else 0
                for a, uf, lf in zip(
                    starts_sep,
                    f.history['xgboost']['UpperCI'],
                    f.history['xgboost']['LowerCI']
                )
            ]
        ) / len(starts_sep)
    )
```

(continues on next page)

(continued from previous page)

```
)
```

```
All confidence intervals for every step are 37.01 units away from the point predictions.
The interval contains 100.00% of the actual values
```

5.1.2 Score default interval

[14]:
```
metrics.msis(
    a = starts_sep,
    uf = f.history['xgboost']['UpperCI'],
    lf = f.history['xgboost']['LowerCI'],
    obs = f.y,
    m = 12,
)
```

[14]:
```
4.026554265078705
```

5.2 Step 2: Backtest Pipeline

- Iterations need to be at least 20 for 95% intervals.
- Length of each prediction in the backtest should match our desired forecast length.

[15]:
```
%%time
backtest_results = backtest_for_resid_matrix(
    f,
    pipeline=pipeline,
    alpha = .05, # default
    jump_back = 1, # default
)
```

```
CPU times: total: 1min 40s
Wall time: 28.5 s
```

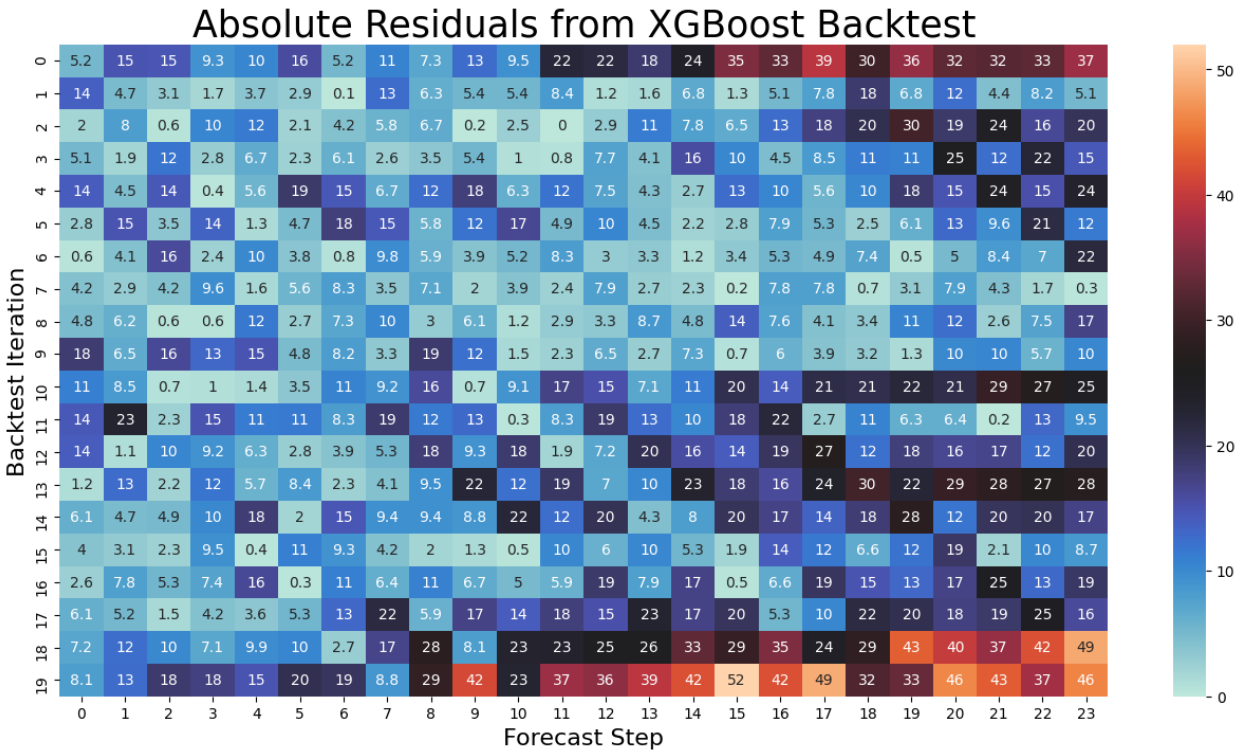
5.3 Step 3: Build Residual Matrix

- Result is matrix shaped 20x24, each row a backtest iteration, each column a forecast step, each value a residual.

[16]:
```
backtest_resid_matrix = get_backtest_resid_matrix(backtest_results)
```

5.3.1 Residual Analytics

[17]:
```
pd.options.display.max_columns = None
fig, ax = plt.subplots(figsize=(16,8))
mat = pd.DataFrame(np.abs(backtest_resid_matrix[0]['xgboost']))
sns.heatmap(
    mat.round(1),
    annot = True,
    ax = ax,
    cmap = sns.color_palette("icefire", as_cmap=True)
)
plt.ylabel('Backtest Iteration',size=16)
plt.xlabel('Forecast Step',size = 16)
plt.title('Absolute Residuals from XGBoost Backtest',size=25)
plt.show()
```

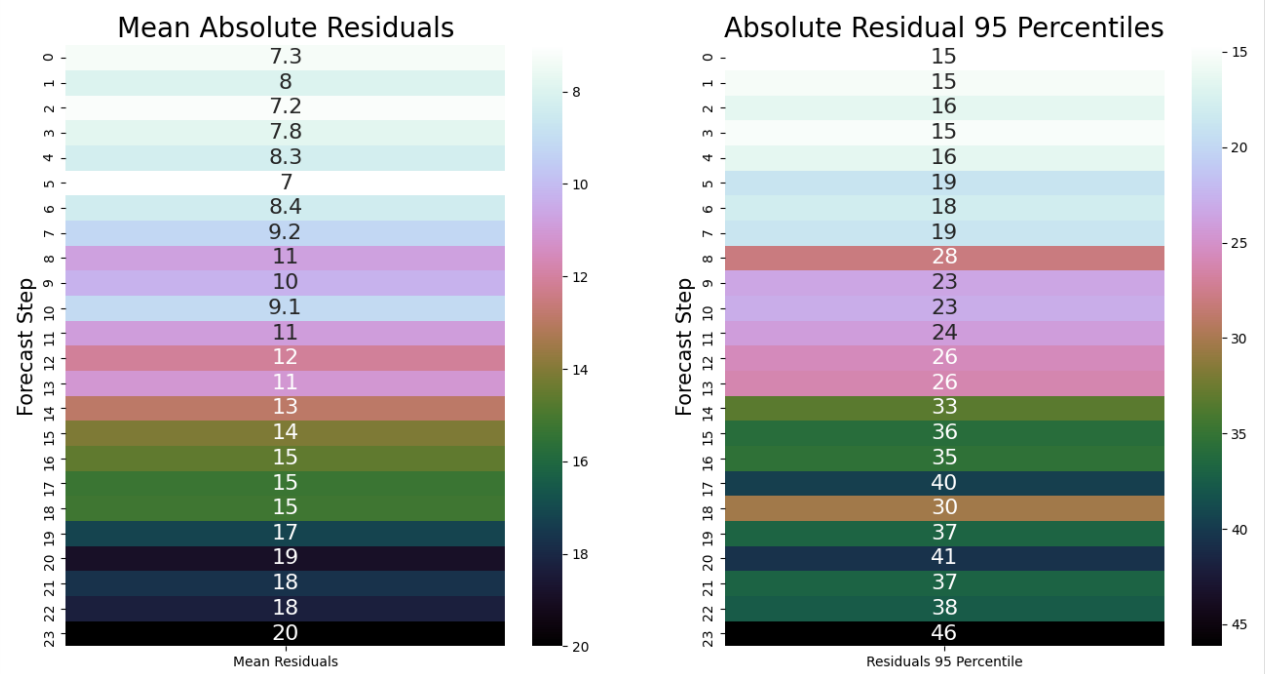


[18]:
```
fig, ax = plt.subplots(1,2,figsize=(16,8))
sns.heatmap(
    pd.DataFrame({'Mean Residuals':mat.mean().round(1)}),
    annot = True,
    cmap = 'cubehelix_r',
    ax = ax[0],
    annot_kws={"fontsize": 16},
)
cbar = ax[0].collections[0].colorbar
cbar.ax.invert_yaxis()
ax[0].set_title('Mean Absolute Residuals',size=20)
ax[0].set_ylabel('Forecast Step',size=15)
```

(continues on next page)

(continued from previous page)

```
ax[0].set_xlabel('')
sns.heatmap(
    pd.DataFrame({'Residuals 95 Percentile':np.percentile(mat, q=95, axis = 0)}),
    annot = True,
    cmap = 'cubehelix_r',
    ax = ax[1],
    annot_kws={"fontsize": 16},
)
cbar = ax[1].collections[0].colorbar
cbar.ax.invert_yaxis()
ax[1].set_title('Absolute Residual 95 Percentiles',size=20)
ax[1].set_ylabel('Forecast Step',size=15)
ax[1].set_xlabel('')
plt.show()
```

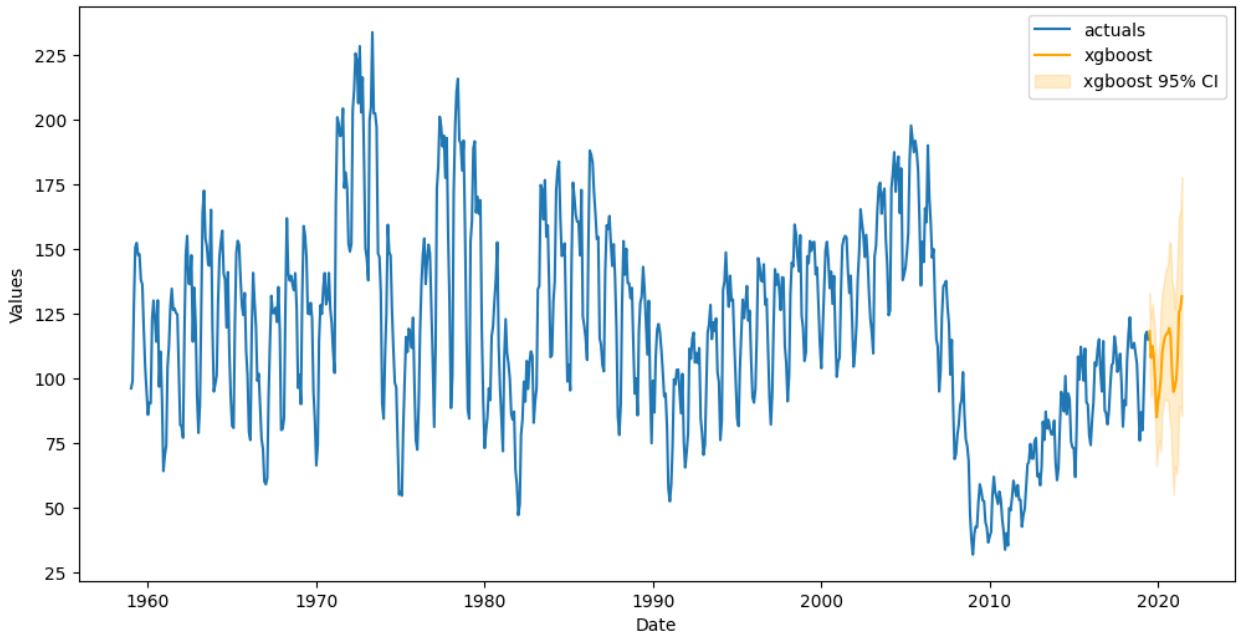


Each step of the forecast will be plus/minus the 95 percentile of the absolute residuals (plot on right).

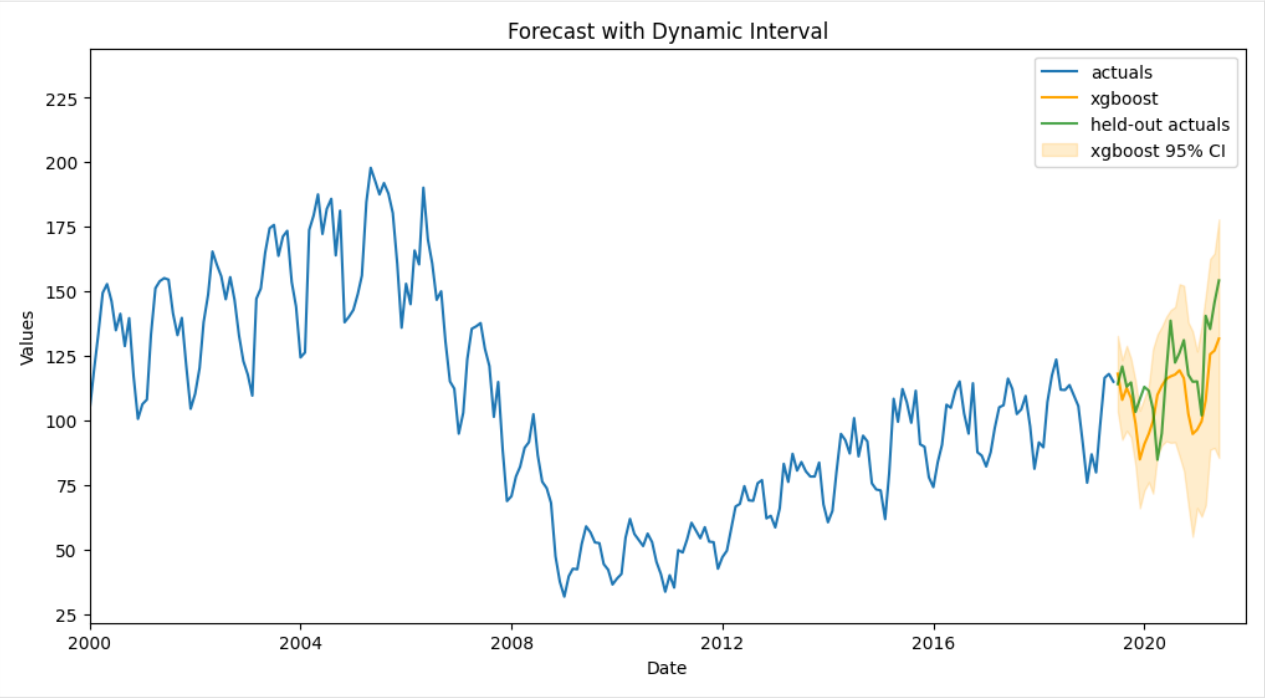
5.4 Step 4: Overwrite Naive Interval with Dynamic Interval

[19]:
```
overwrite_forecast_intervals(f,backtest_resid_matrix=backtest_resid_matrix)
```

[20]:
```
f.plot(ci=True);
```



[21]:
```
fig, ax = plt.subplots(figsize=(12,6))
f.plot(ci=True,models='top_1',order_by='TestSetRMSE',ax=ax)
sns.lineplot(
    y = 'HOUSTNSA',
    x = 'DATE',
    data = starts_sep.reset_index(),
    ax = ax,
    label = 'held-out actuals',
    color = 'green',
    alpha = 0.7,
)
plt.xlim(pd.Timestamp('2000-01-01'),pd.Timestamp('2021-12-01'))
plt.title('Forecast with Dynamic Interval')
plt.show()
```



5.5 Score dynamic interval

[22]:
```
metrics.msis(
    a = starts_sep,
    uf = f.history['xgboost']['UpperCI'],
    lf = f.history['xgboost']['LowerCI'],
    obs = f.y,
    m = 12,
)
```

[22]:
```
3.919628517087574
```

It is a small improvement, but still an improvement!

[23]:
```
print(
    'The intervals are on average {:.2f} units away from the point predictions.'.format(
        np.mean(np.percentile(mat, q=95, axis = 0))
    )

)
print(
    'The interval contains {:.2%} of the actual values'.format(
        np.sum(
            [
                1 if a <= uf and a >= lf else 0
                for a, uf, lf in zip(
                    starts_sep,
                    f.history['xgboost']['UpperCI'],
                    f.history['xgboost']['LowerCI']
```

(continues on next page)

(continued from previous page)

```
                )
            ]
        ) / len(starts_sep)
    )
)
```

```
The intervals are on average 27.36 units away from the point predictions.
The interval contains 87.50% of the actual values
```

5.6 Other Backtest Uses

- We can also use the backtest results to report average error metrics over 20 out-of-sample sets.

[24]:
```
backtest_metrics(backtest_results,mets=['rmse','mae','bias'])[['Average']]
```

[24]:
```
                   Average
Model   Metric
xgboost rmse     14.083597
        mae      12.144780
        bias    239.430706
```

[25]:
```
# actual rmse on out-of-sample data
metrics.rmse(starts_sep,f.history['xgboost']['Forecast'])
```

[25]:
```
16.208569138706174
```

[ ]:

```

CHAPTER

SIX

COMBO MODELING

An introduction to the native ensemble/combo model in scalecast.

[1]:
```
import pandas as pd
import pandas_datareader as pdr
import matplotlib
import matplotlib.pyplot as plt
import seaborn as sns
from dateutil.relativedelta import relativedelta
from scalecast.Forecaster import Forecaster
from scalecast.SeriesTransformer import SeriesTransformer
from scalecast.Pipeline import Transformer, Reverter
from scalecast import GridGenerator
```

Download data from FRED (https://fred.stlouisfed.org/series/HOUSTNSA). This data is interesting due to its strong seasonality and irregular cycles. It measures monthly housing starts in the USA since 1959. Predicting this metric with some series that measures demand for houses could be an interesting extension to be able to explain housing prices. It is a common example series that scalecast uses.

[2]:
```
GridGenerator.get_example_grids(overwrite=True)
df = pdr.get_data_fred('HOUSTNSA',start='1900-01-01',end='2022-12-31')
f = Forecaster(
    y=df['HOUSTNSA'],
    current_dates=df.index,
    future_dates = 24,
    test_length = .1,
)
f
```

[2]:
```
Forecaster(
    DateStartActuals=1959-01-01T00:00:00.000000000
    DateEndActuals=2022-12-01T00:00:00.000000000
    Freq=MS
    N_actuals=768
    ForecastLength=24
    Xvars=[]
    TestLength=76
    ValidationMetric=rmse
    ForecastsEvaluated=[]
    CILevel=None
    CurrentEstimator=mlr
    GridsFile=Grids
```

(continues on next page)

(continued from previous page)

```
)
```

6.1 Preprocess Data

- Difference, seasonal difference, and scale the data.
- Create the object that will revert these transformations.

[3]:
```
# create transformations to model stationary data
transformer = Transformer(
    transformers = [
        ('DiffTransform',1),
        ('DiffTransform',12),
        ('MinMaxTransform',),
    ]
)

reverter = Reverter(
    reverters = [
        ('MinMaxRevert',),
        ('DiffRevert',12),

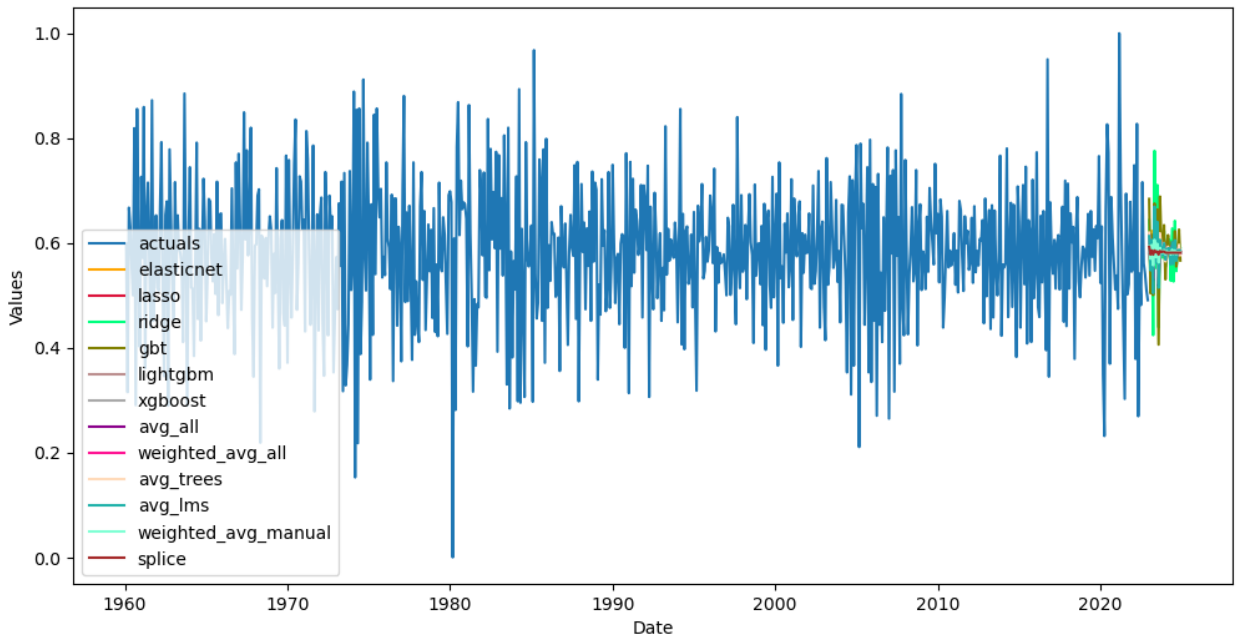
6.3 Combine Evaluated Models

- Below, we see several combination options that scalecast offers. These are just examples and not meant to try to find the absolute best combination for the data.

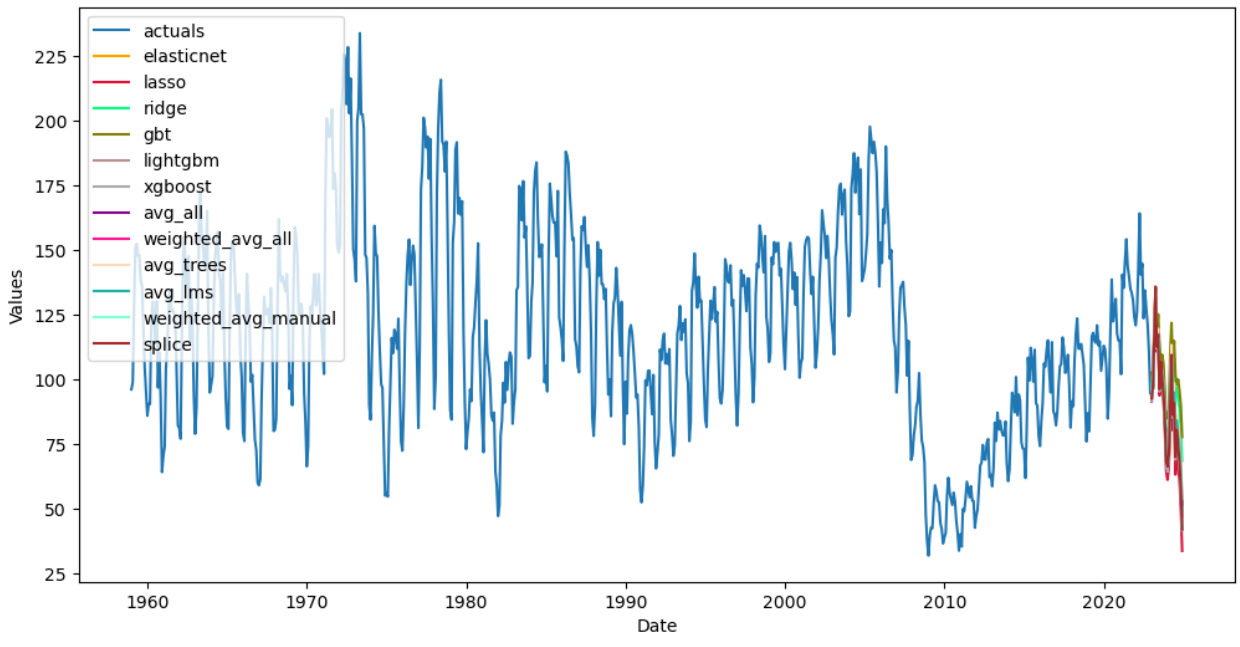
[8]:
```
f.set_estimator('combo')
# simple average of all models
f.manual_forecast(call_me = 'avg_all')
# weighted average of all models where the weights are determined from validation (not␣
↪test) performance
f.manual_forecast(
    how = 'weighted',
    determine_best_by = 'ValidationMetricValue',
    call_me = 'weighted_avg_all',
)
# simple average of a select set of models
f.manual_forecast(models = ['xgboost','gbt','lightgbm'],call_me = 'avg_trees')
# weighted average of a select set of models where the weights are determined from␣
↪validation (not test) performance
f.manual_forecast(models = ['elasticnet','lasso','ridge'],call_me = 'avg_lms')
# weighted average of a select set of models where the weights are manually passed
# weights do not have to add to 1 and they will be rebalanced to do so
f.manual_forecast(
    how = 'weighted',
    models = ['xgboost','elasticnet','lightgbm'],
    weights = (3,2,1),
    determine_best_by = None,
    call_me = 'weighted_avg_manual',
)
# splice (not many other libraries do this) - splice the future point forecasts of two␣
↪or more models together
f.manual_forecast(
    how='splice',
    models = ['elasticnet','lightgbm'],
    splice_points = ['2023-01-01'],
    call_me = 'splice',
)
```

[9]:
```
# plot the forecasts at the series' transformed level
f.plot();
```

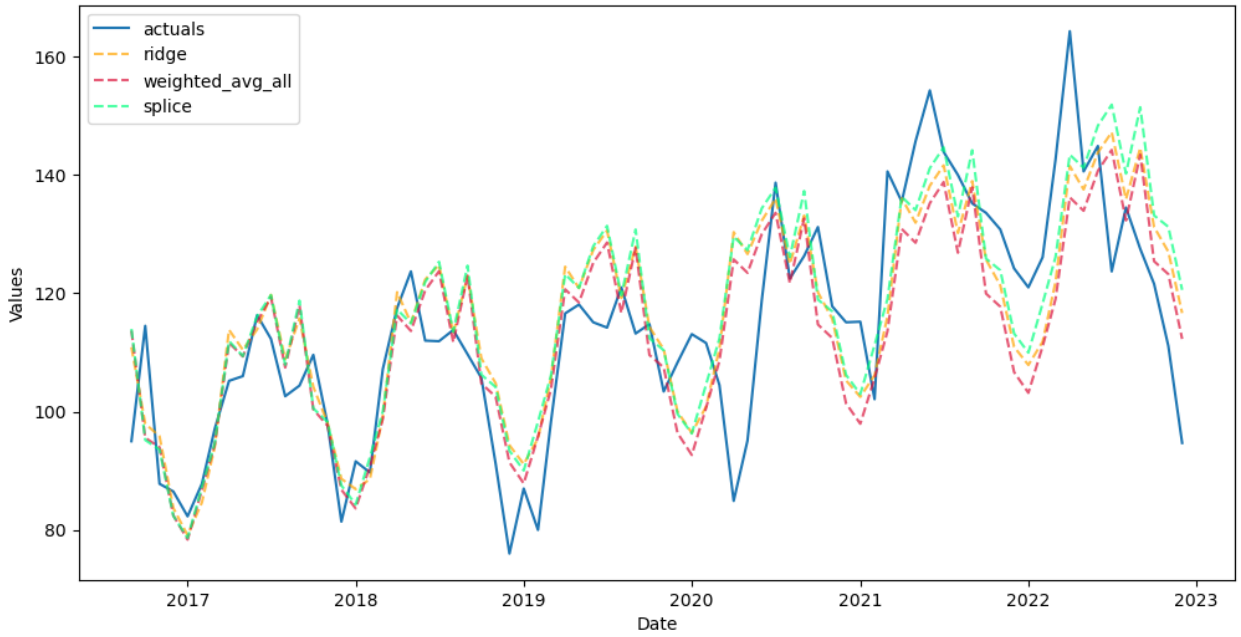


[10]:
```
# revert the transformation
f = reverter.fit_transform(f)
```

[11]:
```
# plot the forecasts at the series' original level
f.plot();
```



[12]:
```
# view performance on test set
f.plot_test_set(models = 'top_3',order_by = 'TestSetRMSE',include_train = False);
```



[ ]:

CHAPTER

SEVEN

CONFIDENCE INTERVALS

This notebook overviews scalecast intervals, which are scored with Mean Scaled Interval Score (MSIS). Lower scores are better. This notebook requires `scalecast>=0.18.0`.

Scalecast uses a naive conformal interval, created from holding out a test-set of data and setting interval ranges from the percentiles of the test-set residuals. This simple approach allows every estimator type to get the same kind of interval. As we will see by scoring the intervals and comparing them to ARIMA intervals from statsmodels, the results are good.

To evaluate the intervals, we leave out a section of each series to score out-of-sample. This is usually not necessary for scalecast, as all models are tested automatically, but the confidence intervals can overfit on any test set stored in the `Forecaster` or `MVForecaster` object due to leakage that occurs when constructing these intervals. Scalecast intervals are compared to ARIMA intervals on the same series in the last section of this notebook and the scalecast intervals, on the whole, perform better. The series used in this example are ordered from easiest-to-hardest to forecast.

Easy Distribution-Free Conformal Intervals for Time Series

Sections:

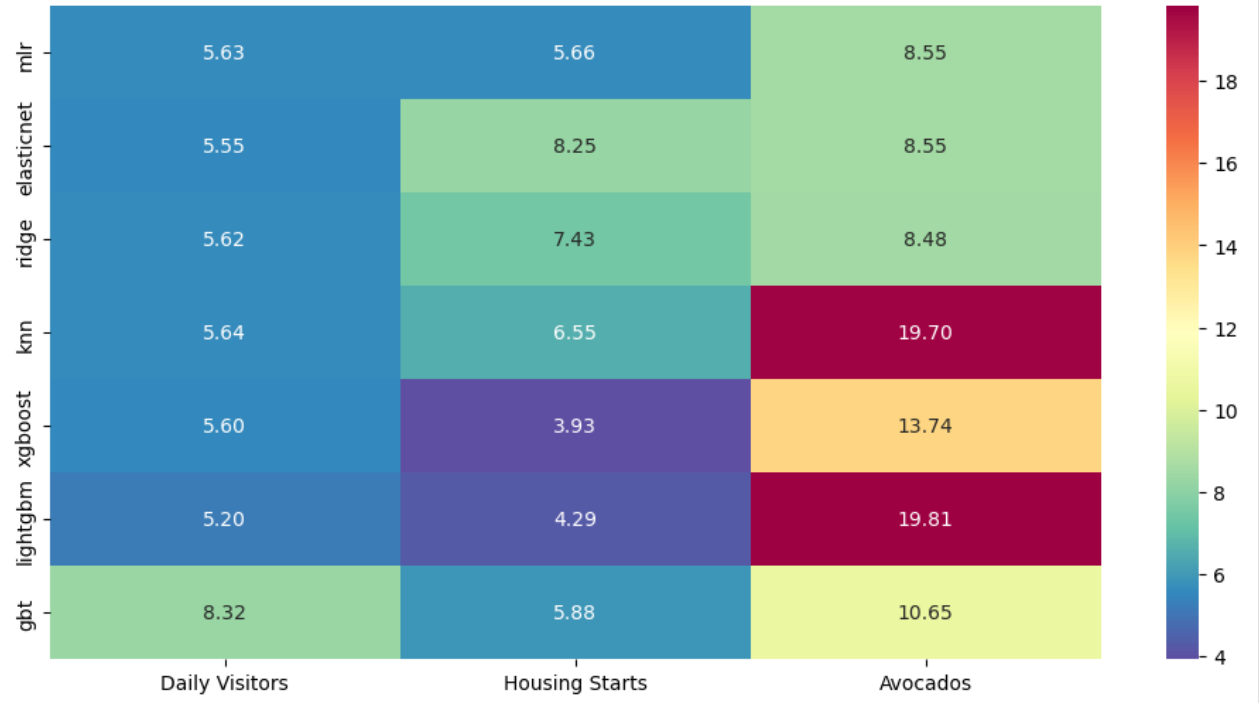
7.4 All Aggregated Results

[38]:
```
_, ax = plt.subplots(figsize=(12,6))
sns.heatmap(
    results,
    annot=True,
    fmt='.2f',
    cmap="Spectral_r",
    ax=ax
)
plt.show()
```



For the most part, the linear models set the best intervals and the boosted tree models were very good or very bad, with GBT more towards the bad side.

7.5 Benchmark Against StatsModels ARIMA

- Confidence intervals come from StatsModels but the auto-ARIMA process is from PMDARIMA.

[39]:
```
from scalecast.auxmodels import auto_arima
```

[40]:
```
all_series = {
    # series,out-of-sample series,seasonal step
    'visitors':[visits,visits_sep,1],
    'housing starts':[starts,starts_sep,12],
    'avocados':[volume,volume_sep,1]
}
arima_conformal_results = pd.DataFrame()
arima_sm_results = pd.DataFrame()
```

[41]:
```
for k, v in all_series.items():
    print(k)
    f = Forecaster(
        y=v[0],
        current_dates=v[0].index,
        future_dates=len(v[1]),
        test_length = len(v[1]),
        cis=True,
    )
    auto_arima(f,m=v[2])
    arima_results = f.export("lvl_fcsts",cis=True)
    # scalecast intervals
    arima_conformal_results.loc[k,'MSIS'] = metrics.msis(
        a = v[1].values,
        uf = arima_results['auto_arima_upperci'].values,
        lf = arima_results['auto_arima_lowerci'].values,
        obs = v[0].values,
        m = v[2],
    )
    # statsmodels intervals
    cis = f.regr.get_forecast(len(v[1])).conf_int()
    arima_sm_results.loc[k,'MSIS'] = metrics.msis(
        a = v[1].values,
        uf = cis.T[1],
        lf = cis.T[0],
        obs = v[0].values,
        m = v[2],
    )
```

```

    highlight_rows,
    axis=1,
)
```

[47]:
```
<pandas.io.formats.style.Styler at 0x7ff0e916eee0>
```

The above table shows which scalecast intervals performed better or worse than the ARIMA interval. Green scores are better, red are worse. The scalecast conformal intervals were on the whole better, but not always. When comparing ARIMA to ARIMA, the confidence intervals from statsmodels performed slightly worse on one series, slightly better on another, and significantly better on the remaining one. The rest of the models run through scalecast usually beat the ARIMA intervals on all datasets, except housing starts. XGBoost and Lightgbm were the only models to always beat the intervals from StatsModels. On the whole, the scalecast interval has a nice showing against the more traditional interval from ARIMA in the StatsModels package.

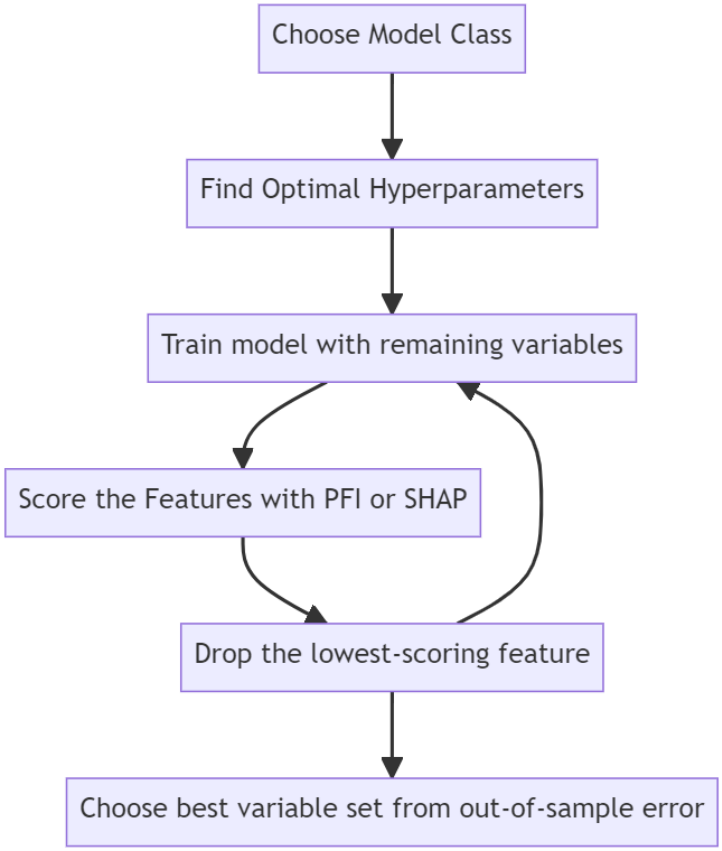
CHAPTER

EIGHT

FEATURE REDUCTION

This notebook demonstrates how to use various feature selection methods using scalecast. The idea behind this example is to reduce the variables stored in the `Forecaster` object to an optimal subset after adding many potentially helpful features to the object.

- Link to data
- See the blog post
- Function documentation link



[1]:
```
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
import seaborn as sns
```

8.3 Reducing with Permutation Feature Importance

- uses the ELI5 package to score feature importances
- eliminates the least-scoring variable (with some scalecast adjustment to account for collinearity), re-trains the model, and evaluates the new error
- by default, the Xvars that return the best error score (according to any metric you want to monitor) is chosen as the optimal set of variables
- to save computation resources, not every variable combination is tried (unlike other reduction techniques)
- to save computation resources, we can set `dynamic_testing = False` and we can set a mininum number of variables to use (the square root of the total number of observations is chosen in this example)
- we can use any sklearn model to reduce variables using this method and we select MLR, KNN, GBT, and SVR in this example

[9]:
```
f.reduce_Xvars(
    method="pfi",
    estimator="mlr",
    keep_at_least="sqrt",
    grid_search=False,
    normalizer="minmax",
    overwrite=False,
)
```

```

```
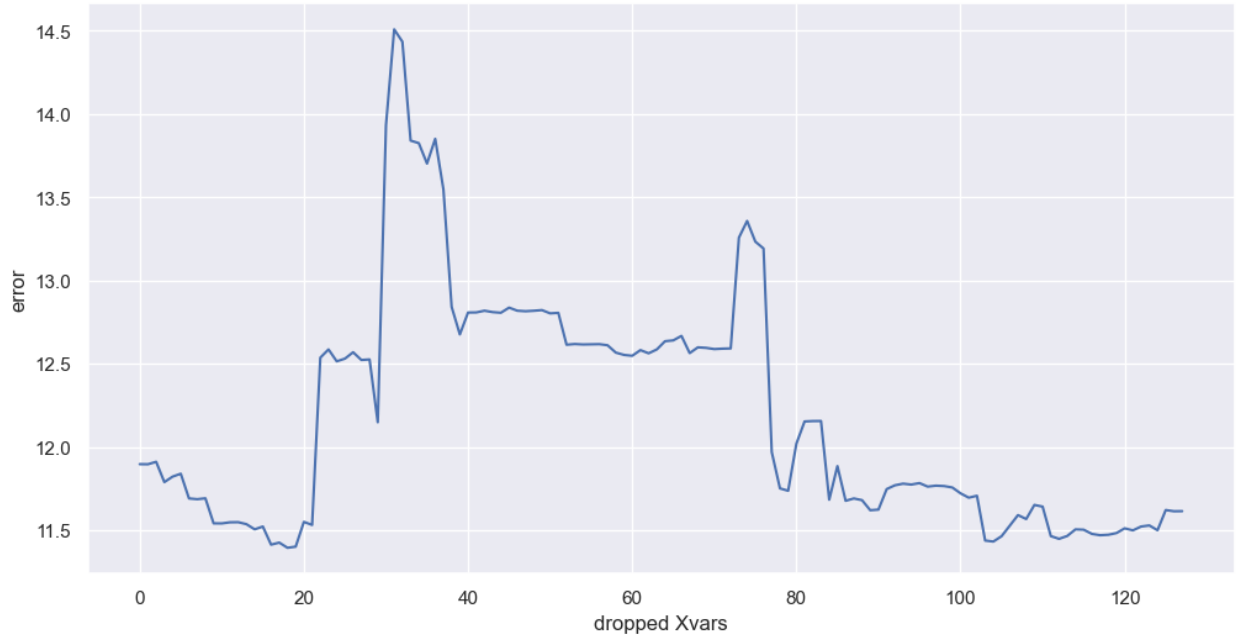
mlr_reduced_vars = f.reduced_Xvars[:]
print(f"mlr with pfi reduced to {len(mlr_reduced_vars)} variables")
```

```
mlr with pfi reduced to 166 variables
```

[11]:
```
plot_reduction_errors(f)
plt.show()
```



The above graph shows that the MLR performs best when about 50 variables are reduced, according to the MAE on the validation set. The order the variables were dropped was based on permutation feature importance. Clearly, too many variables had been added initially and reducing them out made a significant positive difference to the model's performance. Note, the error metric monitored is not from the test set, but from a different out-of-sample slice of data. Later models use the test set to validate the decisions that were made while monitoring this validation metric.

[12]:
```
def reduce_and_save_results(f, model, results):
    f.reduce_Xvars(
        method="pfi",
        estimator=model,
        keep_at_least="sqrt",
        grid_search=True,
        dynamic_testing=False,
        overwrite=False,
    )
    results[model] = [
        f.reduced_Xvars,
        f.pfi_dropped_vars,
        f.pfi_error_values,
        f.reduction_hyperparams,
```

(continues on next page)

(continued from previous page)

```
    ]
```

[ ]:
```
results = {
    "mlr": [
        f.reduced_Xvars,
        f.pfi_dropped_vars,
        f.pfi_error_values,
        f.reduction_hyperparams,
    ]
}

for model in ("knn", "gbt", "svr"):
    print(f"reducing with {model}")
    reduce_and_save_results(f, model, results)
```

```
reducing with knn
```

[ ]:
```
for k, v in results.items():
    print(f"the {k} model chose {len(v[0])} variables")
    sns.lineplot(x=np.arange(0, len(v[1]) + 1, 1), y=v[2], label=k)
plt.xlabel("dropped Xvars")
plt.ylabel("error")
plt.show()
```

Out of the four models we tried using pfi, the gbt model scored the best on the validation set with 136 variables. We will re-train that model with each of the reduced set of variables and see which reduction performs best on the test set. We will use the best-performing model class from the four we tried: gbt. There is no perfect way to choose a set of variables and it is clear that the gbt model performs only marginally different depending on how many variables are dropped, probably because of how the underlying decision tree model can give lower weight to less-important features natively.

[ ]:
```
knn_reduced_vars = results["knn"][0]
gbt_reduced_vars = results["gbt"][0]
svr_reduced_vars = results["svr"][0]
```

8.4 Training a Model Class with All Reduced Variable Sets

[ ]:
```
selected_model = "gbt"
hp = results[selected_model][3]
f.set_estimator(selected_model)
f.manual_forecast(**hp, Xvars="all", call_me=selected_model + "_all_vars")
f.manual_forecast(
    **hp, Xvars=lasso_reduced_vars, call_me=selected_model + "_l1_reduced_vars"
)
f.manual_forecast(
    **hp, Xvars=mlr_reduced_vars, call_me=selected_model + "pfi-mlr_reduced_vars"
)
f.manual_forecast(
    **hp, Xvars=knn_reduced_vars, call_me=selected_model + "pfi-knn_reduced_vars"
)
```

(continues on next page)

(continued from previous page)

```
f.manual_forecast(
    **hp, Xvars=gbt_reduced_vars, call_me=selected_model + "pfi-gbt_reduced_vars"
)
f.manual_forecast(
    **hp, Xvars=svr_reduced_vars, call_me=selected_model + "pfi-svr_reduced_vars"
)
```

[ ]:
```
export_results(f)
```

Although the gbt model with 136 variables performed best out of all tried models on the validation set, on the test set, the 98 variables selected by KNN led to the best performance, followed by using all variables and then the 36 selected from the L1 reduction. This illustrates that even if a reduction decision is made with one estimator class, it can still be useful for another model class.

[ ]:
```
f.plot_test_set(ci=True, order_by="TestSetMAE", include_train=240)
plt.show()
```

8.5 Backtest Best Model

Backtesting shows the average performance of a given model across the last 10 (by default) forecast horizons, using only data before each 120-period forecast to train the model. It's a good way to see if your model generalizes well or just got lucky on the particular test set you fed to it.

[ ]:
```
f.backtest("gbtpfi-knn_reduced_vars")
f.export_backtest_metrics("gbtpfi-knn_reduced_vars")
```

[ ]:
```
f.plot(models="gbtpfi-knn_reduced_vars", ci=True)
plt.show()
```

8.6 Export Reduced Dataset

[ ]:
```
reduced_dataset = f.export_Xvars_df()[['DATE'] + knn_reduced_vars]
reduced_dataset.head(25)
```

8.7 See how often each var was dropped

[ ]:
```
pd.options.display.max_rows = None
all_xvars = f.get_regressor_names()
final_dropped = pd.DataFrame({"Var": all_xvars})
for i, v in f.export("model_summaries").iterrows():
    model = v["ModelNickname"]
    Xvars = v["Xvars"]
    dropped_vars = [x for x in f.get_regressor_names() if x not in Xvars]
    if not dropped_vars:
        continue
```

(continues on next page)

(continued from previous page)

```
    tmp_dropped = pd.DataFrame(
        {"Var": dropped_vars, f"dropped in {model}": [1] * len(dropped_vars)}
    )
    final_dropped = final_dropped.merge(tmp_dropped, on="Var", how="left").fillna(0)
final_dropped["total times dropped"] = final_dropped.iloc[:, 1:].sum(axis=1)
final_dropped = final_dropped.loc[final_dropped["total times dropped"] > 0]
final_dropped = final_dropped.sort_values("total times dropped", ascending=False)
final_dropped = final_dropped.reset_index(drop=True)
final_dropped.iloc[:, 1:] = final_dropped.iloc[:, 1:].astype(int)
final_dropped
```

TEN

HOLT-WINTERS EXPONENTIAL SMOOTHING

This notebook demonstrates running an HWES model in scalecast.

- See the documentation.

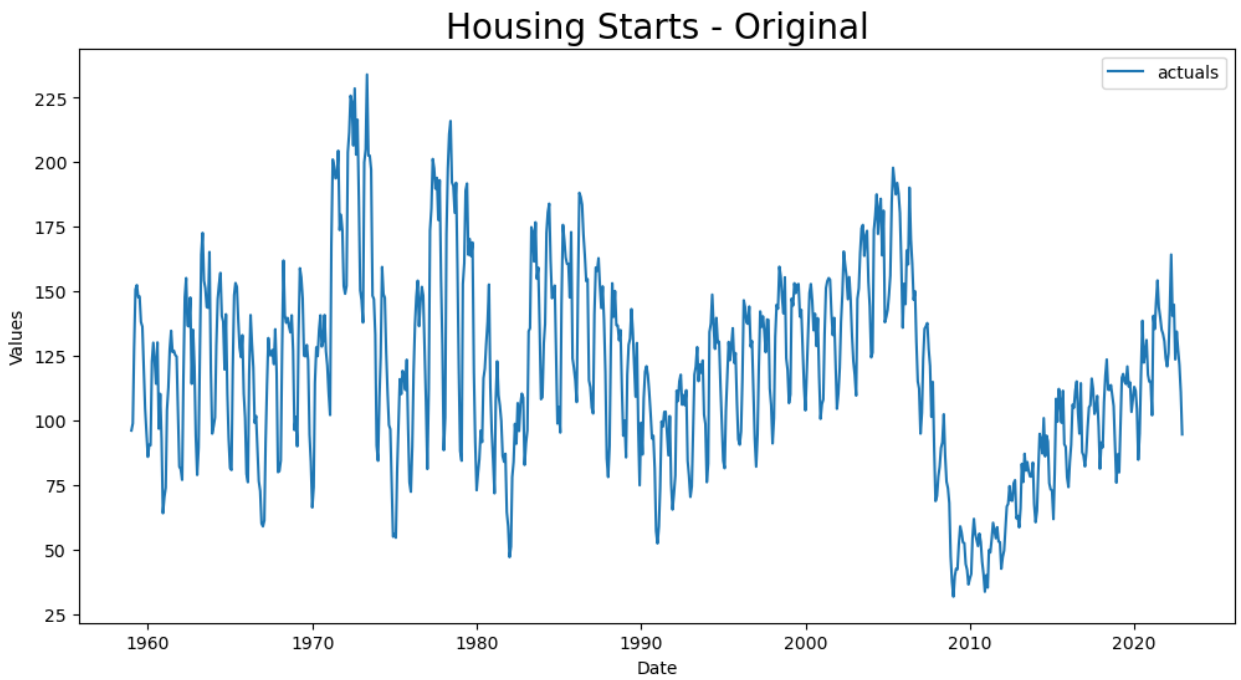
[1]:
```
import pandas as pd
import numpy as np
import pandas_datareader as pdr
import seaborn as sns
import matplotlib
import matplotlib.ticker as ticker
import matplotlib.pyplot as plt
from scalecast.Forecaster import Forecaster
```

Download data from FRED (https://fred.stlouisfed.org/series/HOUSTNSA). This data is interesting due to its strong seasonality and irregular cycles. It measures monthly housing starts in the USA since 1959. Since exponential smoothing generally doesn't need as much data to work effectively, we start the series in 2010, where it has a clear trend and seasonality.

[2]:
```
df = pdr.get_data_fred('HOUSTNSA',start='1959-01-01',end='2022-12-31')
f = Forecaster(
    y=df['HOUSTNSA'],
    current_dates=df.index,
    future_dates = 24,
    test_length = 24,
    cis = True,
)
f
```

[2]:
```
Forecaster(
    DateStartActuals=1959-01-01T00:00:00.000000000
    DateEndActuals=2022-12-01T00:00:00.000000000
    Freq=MS
    N_actuals=768
    ForecastLength=24
    Xvars=[]
    TestLength=24
    ValidationMetric=rmse
    ForecastsEvaluated=[]
    CILevel=0.95
    CurrentEstimator=mlr
    GridsFile=Grids
)
```

[3]:
```
f.plot()
plt.title('Housing Starts - Original',size=20)
plt.show()
```



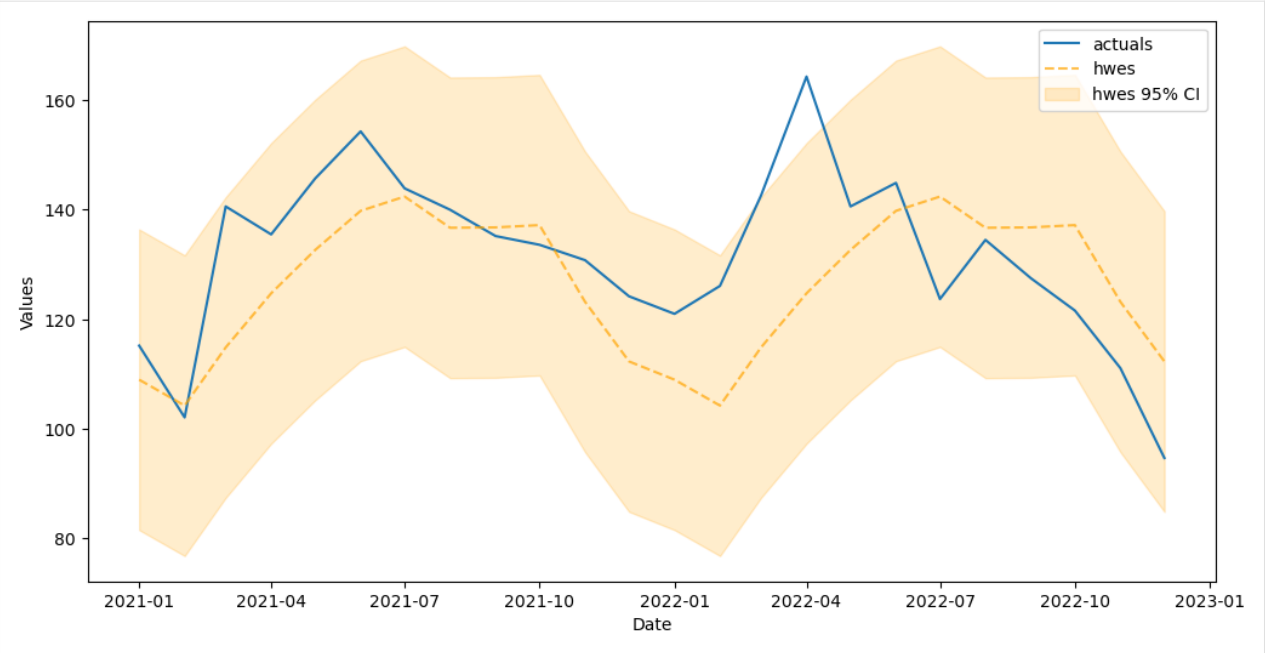
10.1 Forecast

[4]:
```
hwes_grid = {
    'trend':['add','mul',None],
    'seasonal':['add','mul',None],
    'use_boxcox':[True,False],
}
```

[5]:
```
f.set_estimator('hwes')
f.ingest_grid(hwes_grid)
f.cross_validate(k=10) # 10-fold cv to find optimal hyperparams
f.auto_forecast()
f.best_params
```

[5]:
```
{'trend': None, 'seasonal': 'add', 'use_boxcox': False}
```

[6]:
```
f.plot_test_set(ci=True,include_train=False);
```



10.2 Model Summary

[7]:
```
f.regr.summary()
```

[7]:
```

CHAPTER

ELEVEN

LINKEDIN SILVERKITE

Silverkite is a model from the greykite package, developed by LinkedIn. It is considered an automated modeling procedure, like Facebook Prophet. It has its own database of holidays it forecasts with and attempts to tune its parameters automatically. The model itself is a type of linear regression with changepoints and regularization.

In this notebook, the following concepts are covered:

1. Loading Forecaster objects with external regressors
2. Forecasting with default silverkite model
3. Modifying changepoints in silverkite model
4. Tuning silverkite model
5. Forecasting on differenced data
6. Model summaries

- install greykite: `pip install greykite`
- read more about grekite: https://engineering.linkedin.com/blog/2021/greykite–a-flexible–intuitive–and-fast-forecasting-library
- see the combo notebook for an overview of this dataset with EDA

[1]:
```
import pandas as pd
import pandas_datareader as pdr
import matplotlib
import matplotlib.pyplot as plt
import seaborn as sns
from dateutil.relativedelta import relativedelta
from scalecast.Forecaster import Forecaster
from scalecast.util import find_optimal_transformation
from scalecast.Pipeline import Pipeline
```

[2]:
```
df = pdr.get_data_fred(['HOUSTNSA','JHDUSRGDPBR'],start='1900-01-01',end='2021-12-31')
df['JHDUSRGDPBR'] = df['JHDUSRGDPBR'].fillna(method='ffill').fillna(0)
f = Forecaster(y=df['HOUSTNSA'],current_dates=df.index)
f
```

[2]:
```
Forecaster(
    DateStartActuals=1959-01-01T00:00:00.000000000
    DateEndActuals=2021-12-01T00:00:00.000000000
    Freq=MS
    N_actuals=756
    ForecastLength=0
    Xvars=[]
```

(continues on next page)

(continued from previous page)

```
    TestLength=0
    ValidationMetric=rmse
    ForecastsEvaluated=[]
    CILevel=None
    CurrentEstimator=mlr
    GridsFile=Grids
)
```

11.1 Prepare Forecast

11.1.1 Prepare the Recession Indicator

- use as an exogenous regressor

[3]:
```
# prepare recession indicator for future
# assume no future recessions in next two years
recessions = df.reset_index()[['DATE','JHDUSRGDPBR']]
fut_recessions = pd.DataFrame({
    'DATE':pd.date_range(
        start=recessions['DATE'].max(),
        periods=25,
        freq='MS'
    ).values[1:],
    'JHDUSRGDPBR':[0]*24}
)
recessions = pd.concat([recessions,fut_recessions])
recessions.tail()
```

[3]:
```
         DATE  JHDUSRGDPBR
19 2023-08-01          0.0
20 2023-09-01          0.0
21 2023-10-01          0.0
22 2023-11-01          0.0
23 2023-12-01          0.0
```

11.1.2 Load Object with Parameters and Regressors

- Forecast length: 24 periods (two years)
- Test length: 24 periods
- External recession indicator
- Conformal confidence intervals

[4]:
```
f.generate_future_dates(24)
f.set_test_length(24)
f.ingest_Xvars_df(recessions,date_col="DATE") # let the model consider recesssions
f.add_ar_terms(range(24,37)) # we can use direct autoregressive forecasting with␣
↪silverkite
```

(continues on next page)

(continued from previous page)

```
f.eval_cis()
f
```

[4]:
```
Forecaster(
    DateStartActuals=1959-01-01T00:00:00.000000000
    DateEndActuals=2021-12-01T00:00:00.000000000
    Freq=MS
    N_actuals=756
    ForecastLength=24
    Xvars=['JHDUSRGDPBR', 'AR24', 'AR25', 'AR26', 'AR27', 'AR28', 'AR29', 'AR30', 'AR31',
↪ 'AR32', 'AR33', 'AR34', 'AR35', 'AR36']

```

One seasonal difference chosen.

11.2 Apply the silverkite model

[6]:
```
silverkite_grid = {
    'changepoints':[2,None],
    'Xvars':[None,'all']
}
```

[7]:
```
def forecaster(f):
    f.set_estimator('silverkite')
    f.ingest_grid(silverkite_grid)
    f.cross_validate(
```

(continues on next page)

(continued from previous page)

```
        k=3,
        verbose=True,
        test_length=24,
    )
    f.auto_forecast()
    matplotlib.use("nbAgg")
    %matplotlib inline
```

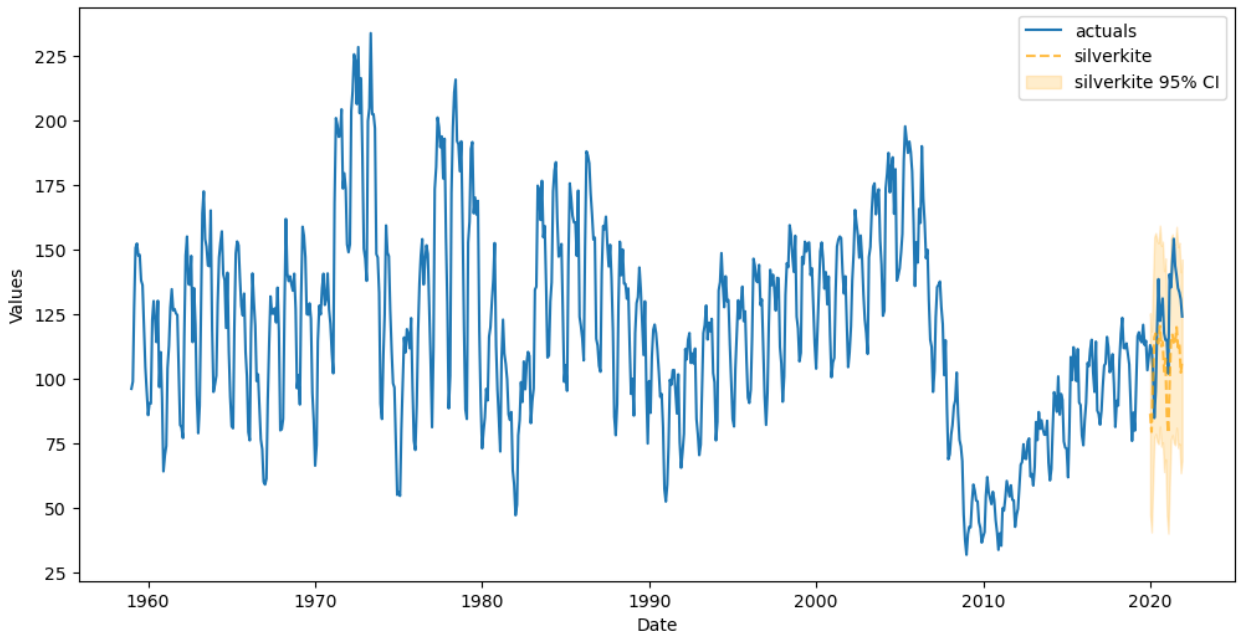
[8]:
```
pipeline = Pipeline(
    steps = [
        ('Transform',transformer),
        ('Forecast',forecaster),
        ('Revert',reverter),
    ]
)
```

[9]:
```
f = pipeline.fit_predict(f)
```

```
Num hyperparams to try for the silverkite model: 4.
Fold 0: Train size: 696 (1960-01-01 00:00:00 - 2017-12-01 00:00:00). Test Size: 24 (2018-
↪01-01 00:00:00 - 2019-12-01 00:00:00).
Fold 1: Train size: 672 (1960-01-01 00:00:00 - 2015-12-01 00:00:00). Test Size: 24 (2016-
↪01-01 00:00:00 - 2017-12-01 00:00:00).
Fold 2: Train size: 648 (1960-01-01 00:00:00 - 2013-12-01 00:00:00). Test Size: 24 (2014-
↪01-01 00:00:00 - 2015-12-01 00:00:00).
Chosen paramaters: {'changepoints': 2, 'Xvars': None}.
```

Now we can see the results plotted.

[10]:
```
f.plot_test_set(ci=True)
plt.show()
```



[11]:
```
f.plot(ci=True)
plt.show()
```

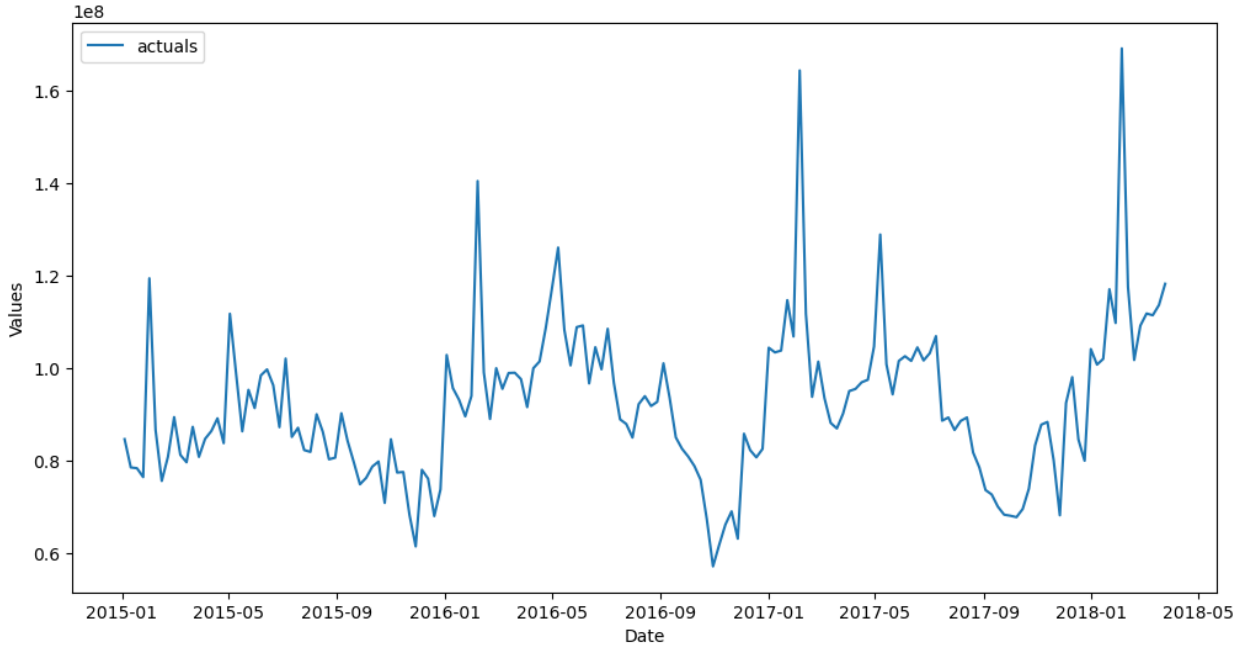
12.2 Problem 2 - Multivariate Forecasting

[5]:
```
data = pd.read_csv('avocado.csv')
```

[6]:
```
# demand
vol = data.groupby('Date')['Total Volume'].sum()
# price
price = data.groupby('Date')['AveragePrice'].sum()

fvol = Forecaster(
    y = vol,
    current_dates = vol.index,
    test_length = 13,
    validation_length = 13,
    future_dates = 13,
    metrics = ['rmse','r2'],
)
fprice = Forecaster(
    y = price,
    current_dates = price.index,
    future_dates = 13,
)
```

[7]:
```
fvol.plot()
plt.show()
```



[8]:
```
transformer, reverter = find_optimal_transformation(
    fvol,
    set_aside_test_set=True, # prevents leakage so we can benchmark the resulting models␣
↪fairly
    return_train_only = True, # prevents leakage so we can benchmark the resulting␣
↪models fairly
    verbose=True,
    detrend_kwargs=[

CHAPTER

THIRTEEN

META PROPHET

Prophet is a procedure for forecasting time series data based on an additive model where non-linear trends are fit with yearly, weekly, and daily seasonality, plus holiday effects. It works best with time series that have strong seasonal effects and several seasons of historical data. Prophet is robust to missing data and shifts in the trend, and typically handles outliers well.It is designed to se automatically find a good set of hyperparameters for the model in an effort to make forrecast for time series with seasonality and trends.

The Prophet model is not autoregressive, like ARIMA, exponential smoothing, and the other methods we study in a typical time series course (including my own).

The 3 components are:

1. The trend g(t) which can be either linear or logistic.
2. The seasonality s(t), modeled using a Fourier series.
3. The holiday component h(t), which is essentially a one-hot vector "dotted" with a vector of weights, each representing the contribution from their respective holiday.

In this notebook, following concepts are covered:
- Loading time-series
- EDA
- Preparing the data for modeling
- Implementing prophet model
- Evaluating the results

Data: https://www.kaggle.com/datasets/bobnau/daily-website-visitors
Install prophet: `pip install prophet`

Special thanks to Zohoor Nezhad Halafi for contributing this notebook! Connect with her on LinkedIn.

[1]:
```
import pandas as pd
import numpy as np
import seaborn as sns
import matplotlib.pyplot as plt
from scalecast.Forecaster import Forecaster

sns.set(rc={'figure.figsize':(16,8)})
```

13.1 Loading time series

[2]:
```
data = pd.read_csv('daily-website-visitors.csv',parse_dates=['Date'])
```

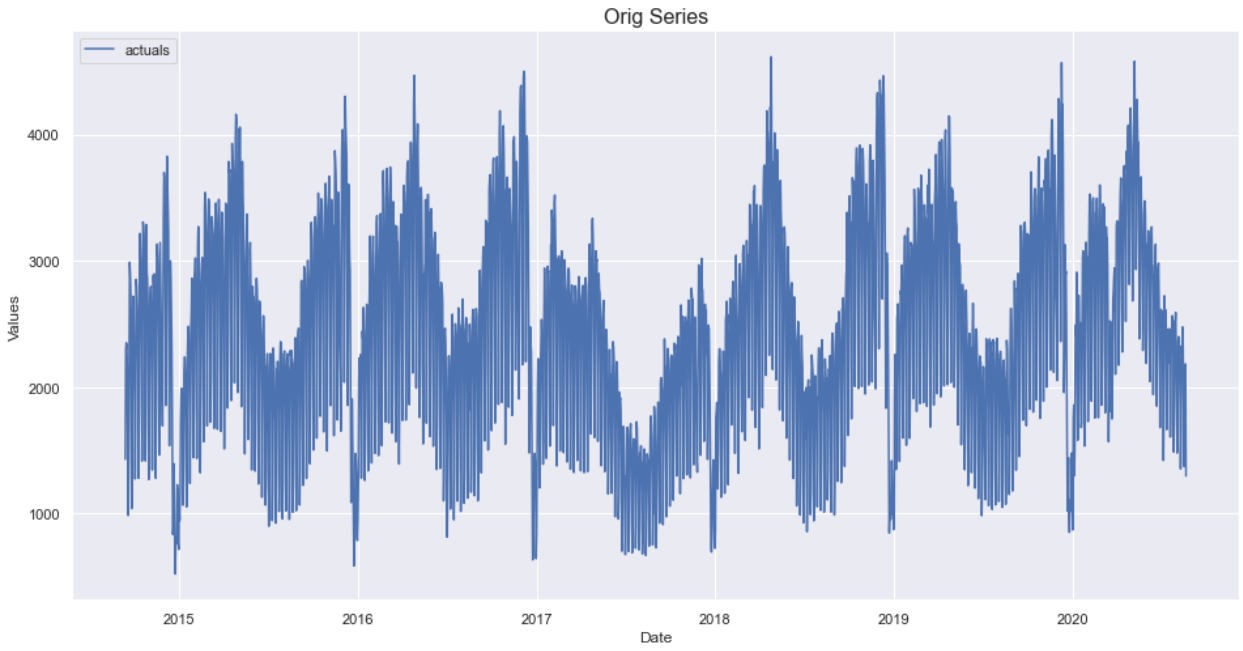
[3]:
```
data=data[['First.Time.Visits','Date']]
```

[4]:
```
data.head()
```

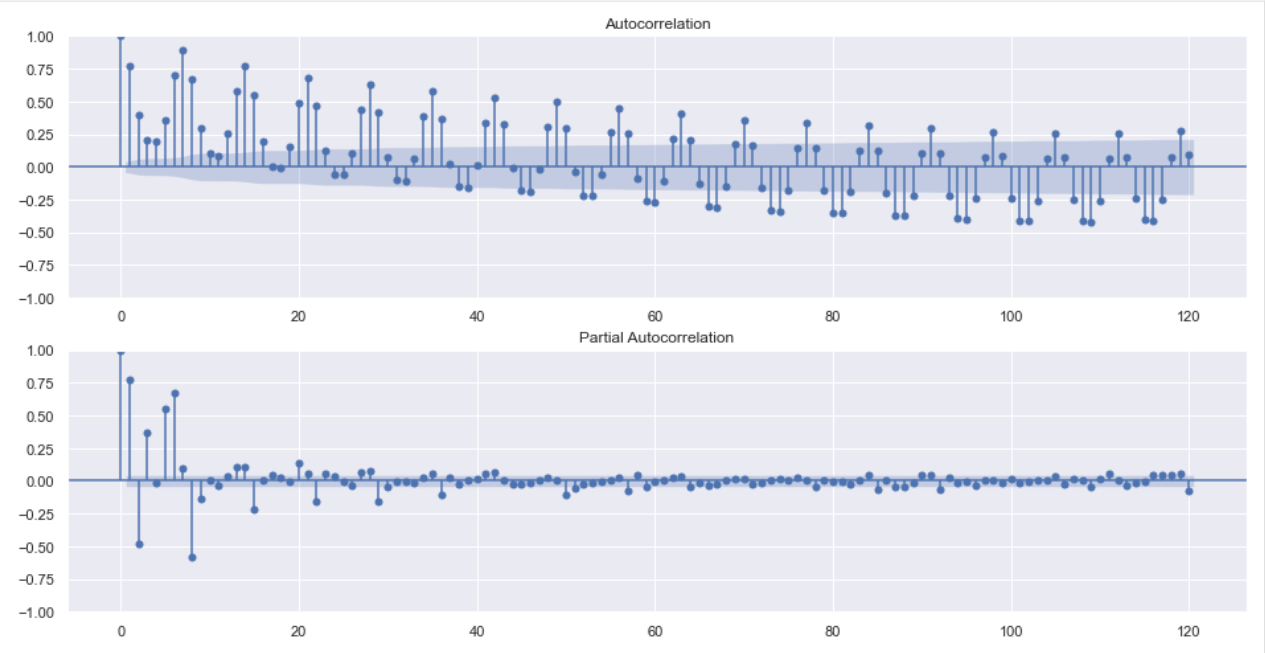
[4]:
```
   First.Time.Visits       Date
0               1430 2014-09-14
1               2297 2014-09-15
2               2352 2014-09-16
3               2327 2014-09-17
4               2130 2014-09-18
```

13.2 EDA

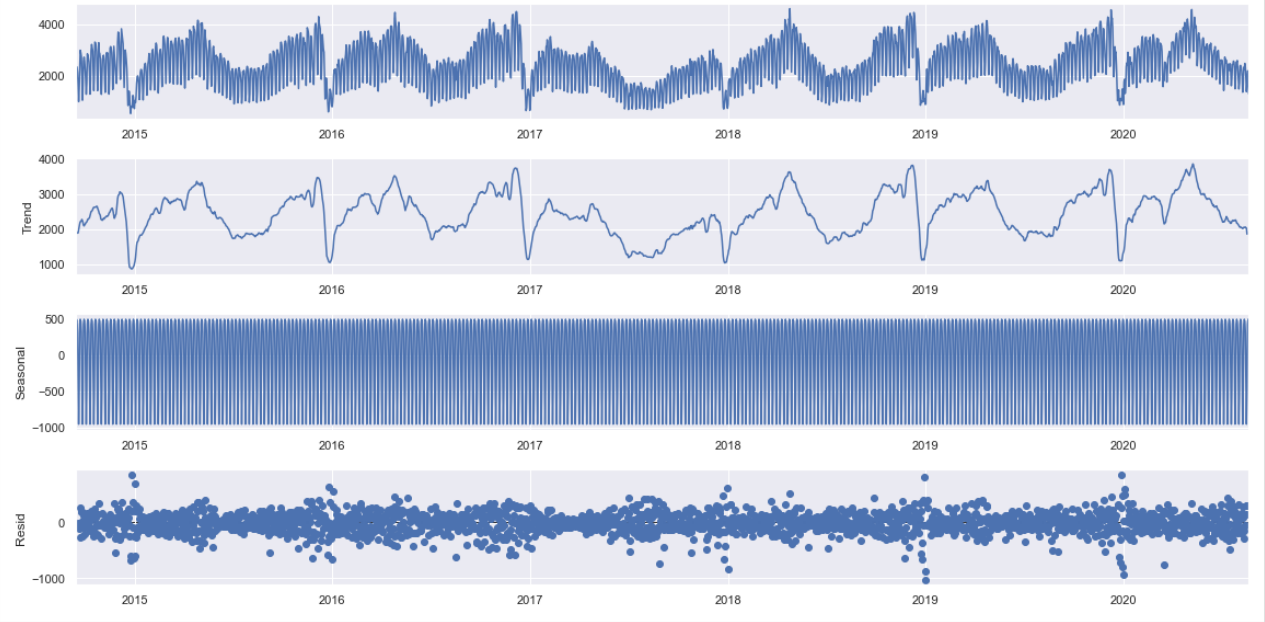
[5]:
```
f=Forecaster(y=data['First.Time.Visits'],current_dates=data['Date'])
f.plot()
plt.title('Orig Series',size=16)
plt.show()
```



[7]:
```
figs, axs = plt.subplots(2, 1)
f.plot_acf(ax=axs[0],lags=120)
f.plot_pacf(ax=axs[1],lags=120)
plt.show()
```



[8]:
```
f.seasonal_decompose().plot()
plt.show()
```



ADF Test

[9]:
```
critical_pval = 0.05
print('-'*100)
print('Augmented Dickey-Fuller results:')
stat, pval, _, _, _, _ = f.adf_test(full_res=True)
print('the test-stat value is: {:.2f}'.format(stat))
print('the p-value is {:.4f}'.format(pval))
print('the series is {}'.format('stationary' if pval < critical_pval else 'not stationary
```

(continues on next page)

(continued from previous page)

```
↪'))
print('-'*100)
```

```
----------------------------------------------------------------------------------------------------
↪-----------
Augmented Dickey-Fuller results:
the test-stat value is: -4.48
the p-value is 0.0002
the series is stationary
----------------------------------------------------------------------------------------------------
↪-----------
```

13.3 Preparing the data for modeling

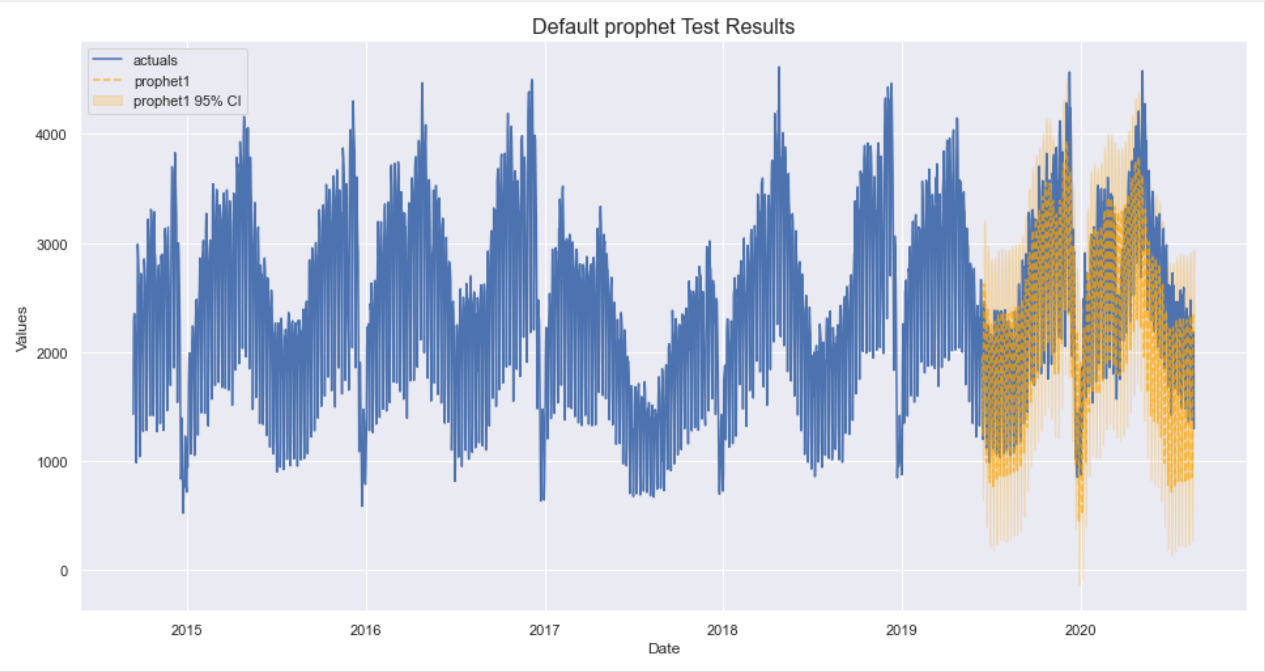
[10]:
```
f.generate_future_dates(60)
f.set_test_length(.2)
f.set_estimator('prophet')
f
```

[10]:
```
Forecaster(
    DateStartActuals=2014-09-14T00:00:00.000000000
    DateEndActuals=2020-08-19T00:00:00.000000000
    Freq=D
    N_actuals=2167
    ForecastLength=60
    Xvars=[]
    Differenced=0
    TestLength=433
    ValidationLength=1
    ValidationMetric=rmse
    ForecastsEvaluated=[]
    CILevel=0.95
    BootstrapSamples=100
    CurrentEstimator=prophet
)
```

13.4 Forecasting

[11]:
```
f.manual_forecast(call_me='prophet1')
```

[12]:
```
f.plot_test_set(ci=True,models='prophet1')
plt.title('Default prophet Test Results',size=16)
plt.show()
```

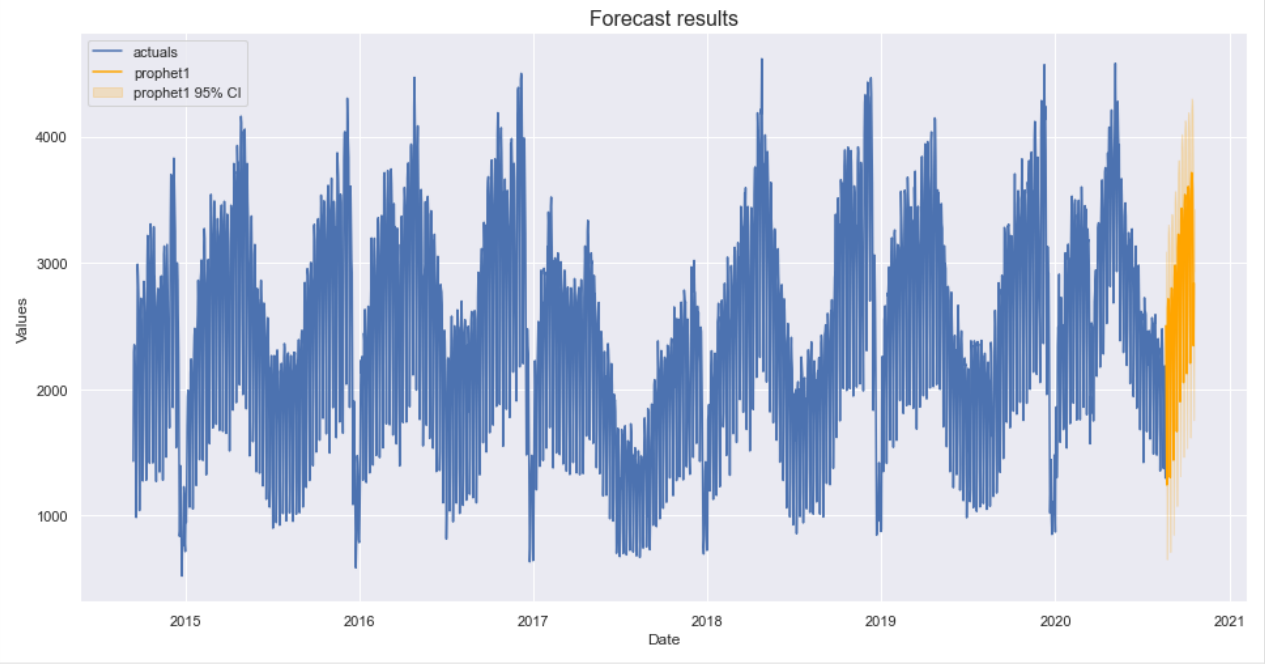


[15]:
```
results = f.export('model_summaries')
results[['TestSetRMSE','InSampleRMSE','TestSetMAPE','InSampleMAPE']]
```

[15]:

	TestSetRMSE	InSampleRMSE	TestSetMAPE	InSampleMAPE
0	403.968233	283.145403	0.136388	0.104243

[14]:
```
f.plot(ci=True,models='prophet1')
plt.title('Forecast results',size=16)
plt.show()
```



```
[ ]:
```

CHAPTER

FOURTEEN

MULTIVARIATE FORECASTING

This notebook outlines an example of scalecast using multiple series to forecast one another using scikit-learn models.

The data is available on Kaggle: https://www.kaggle.com/datasets/neuromusic/avocado-prices
See the blog post:
https://towardsdatascience.com/multiple-series-forecast-them-together-with-any-sklearn-model-96319d46269

[1]:
```
import pandas as pd
import numpy as np
import seaborn as sns
import matplotlib
import matplotlib.ticker as ticker
import matplotlib.pyplot as plt
from scalecast.Forecaster import Forecaster
from scalecast.MVForecaster import MVForecaster
from scalecast.multiseries import export_model_summaries
from scalecast import GridGenerator
```

[2]:
```
# read data
data = pd.read_csv('avocado.csv',parse_dates=['Date']).sort_values(['Date'])
# sort appropriately (not doing this could cause issues)
data = data.sort_values(['region','type','Date'])
```

We will be forecasting the organic and conventional avocado sales from California only.

[3]:
```
data_cali = data.loc[data['region'] == 'California']
data_cali_org = data_cali.loc[data_cali['type'] == 'organic']
data_cali_con = data_cali.loc[data_cali['type'] == 'conventional']
```

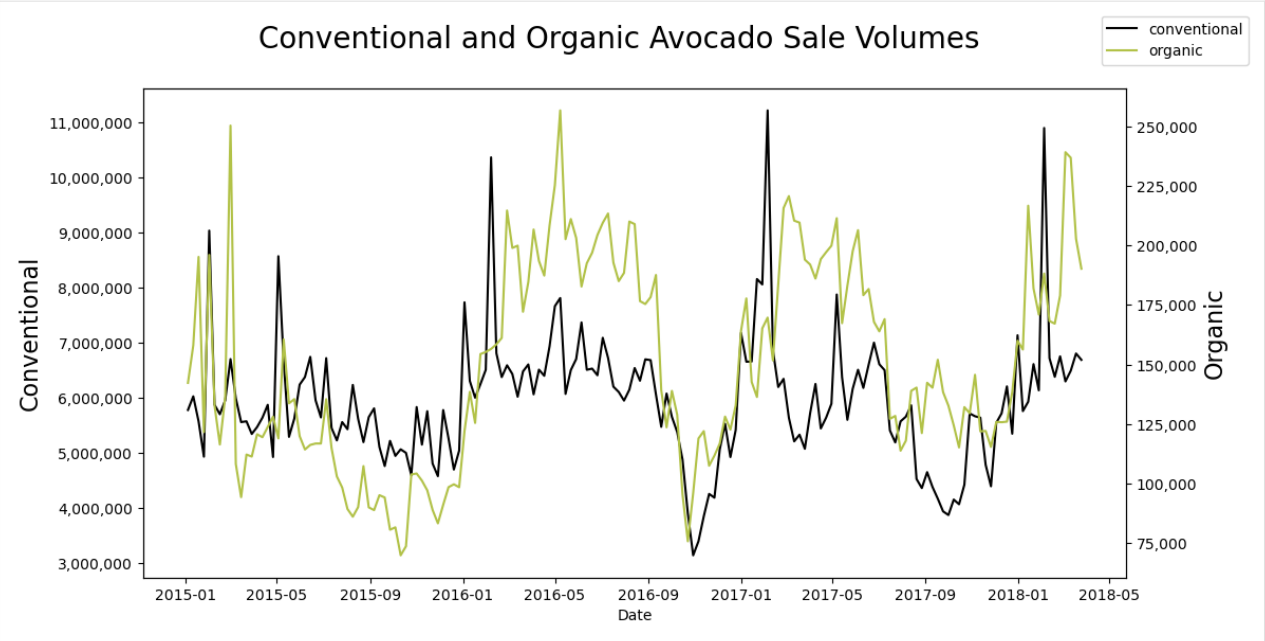
14.1 Choose Models and Import Validation Grids

[4]:
```
# download template validation grids (will not overwrite existing Grids.py file by␣
↪default)
models = ('mlr','elasticnet','knn','rf','gbt','xgboost','mlp')
GridGenerator.get_example_grids()
GridGenerator.get_mv_grids()
```

14.2 EDA

14.2.1 Plot

[5]:
```
fig, ax = plt.subplots(figsize=(12,6))
sns.lineplot(
    x='Date',
    y='Total Volume',
    data=data_cali_con,
    label='conventional',
    ax=ax,
    color='black',
    legend=False
)
plt.ylabel('Conventional',size=16)
ax2 = ax.twinx()
sns.lineplot(
    x='Date',
    y='Total Volume',
    data=data_cali_org,
    label='organic',
    ax=ax2,
    color='#B2C248',
    legend=False
)
ax.figure.legend()
plt.ylabel('Organic',size=16)
ax.yaxis.set_major_formatter(ticker.StrMethodFormatter('{x:,.0f}'))
ax2.yaxis.set_major_formatter(ticker.StrMethodFormatter('{x:,.0f}'))
plt.suptitle('Conventional and Organic Avocado Sale Volumes',size=20)
plt.show()
```



14.2.2 Examine Correlation between the series

[6]:
```
corr = np.corrcoef(data_cali_org['Total Volume'].values,data_cali_con['Total Volume'].
↪values)[0,1]
print('{:.2%}'.format(corr))
```

```
48.02%
```

14.2.3 Load into Forecaster from scalecast

[7]:
```
fcon = Forecaster(
    y=data_cali_con['Total Volume'],
    current_dates = data_cali_con['Date'],
    test_length = .2,
    future_dates = 52,
    validation_length = 4,
    metrics = ['rmse','r2'],
    cis = True,
)
fcon
```

[7]:
```
Forecaster(
    DateStartActuals=2015-01-04T00:00:00.000000000
    DateEndActuals=2018-03-25T00:00:00.000000000
    Freq=W-SUN
    N_actuals=169
    ForecastLength=52
    Xvars=[]
    TestLength=33
    ValidationMetric=rmse
```

(continues on next page)

(continued from previous page)

```
    ForecastsEvaluated=[]
    CILevel=0.95
    CurrentEstimator=mlr
    GridsFile=Grids
)
```

[8]:
```
forg = Forecaster(
    y=data_cali_org['Total Volume'],
    current_dates = data_cali_org['Date'],
    test_length = .2,
    future_dates = 52,
    validation_length = 4,
    metrics = ['rmse','r2'],
    cis = True,
)
forg
```

[8]:
```
Forecaster(
    DateStartActuals=2015-01-04T00:00:00.000000000
    DateEndActuals=2018-03-25T00:00:00.000000000
    Freq=W-SUN
    N_actuals=169
    ForecastLength=52
    Xvars=[]
    TestLength=33
    ValidationMetric=rmse
    ForecastsEvaluated=[]
    CILevel=0.95
    CurrentEstimator=mlr
    GridsFile=Grids
)
```

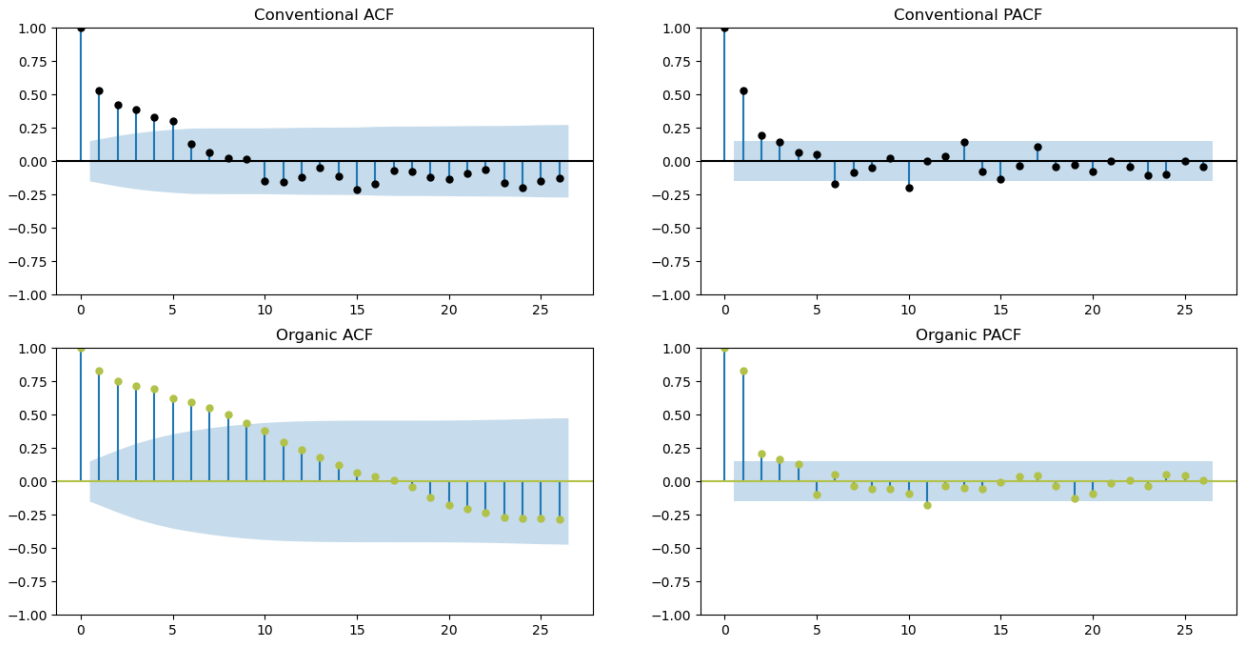
14.2.4 ACF and PACF Plots

[9]:
```
figs, axs = plt.subplots(2, 2,figsize=(16,8))
fcon.plot_acf(
    ax=axs[0,0],
    title='Conventional ACF',
    lags=26,
    color='black'
)
fcon.plot_pacf(
    ax=axs[0,1],
    title='Conventional PACF',
    lags=26,
    color='black',
    method='ywm'
)
forg.plot_acf(
    ax=axs[1,0],
    title='Organic ACF',
```

(continues on next page)

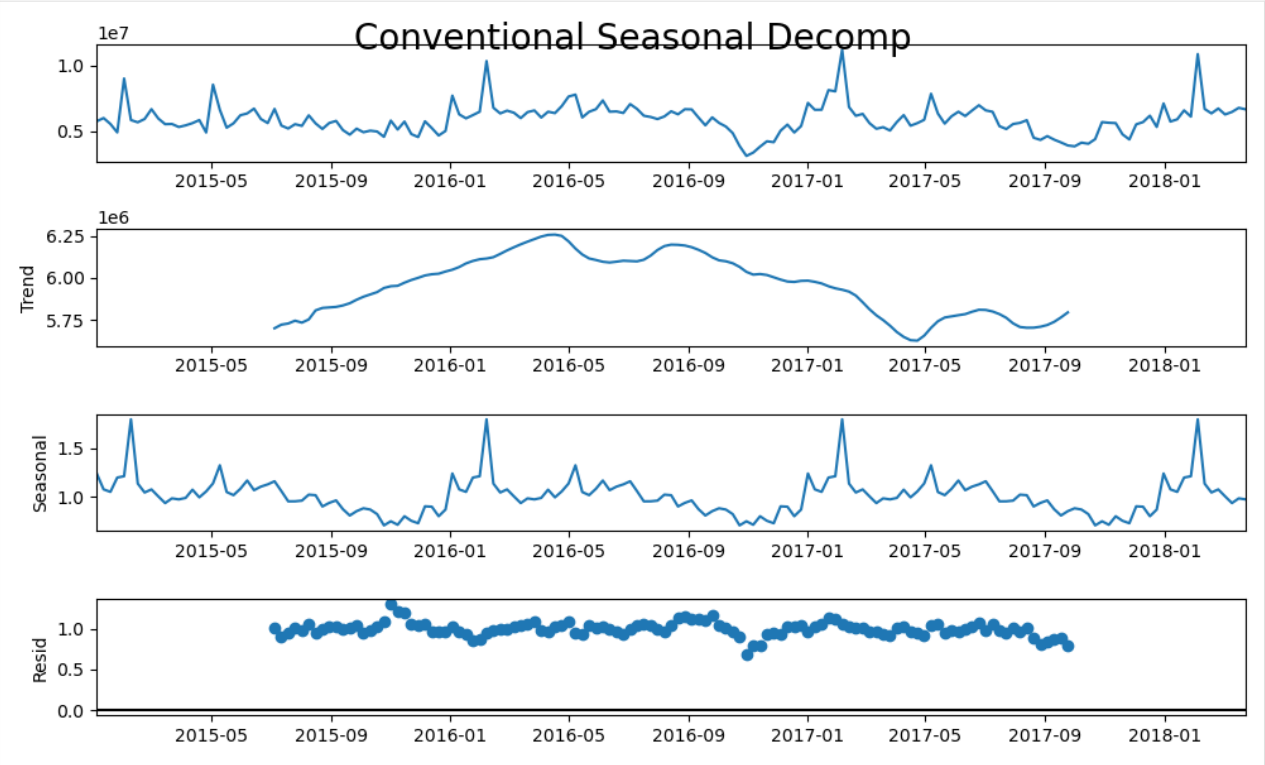
(continued from previous page)

```
    lags=26,
    color='#B2C248'
)
forg.plot_pacf(
    ax=axs[1,1],
    title='Organic PACF',
    lags=26,
    color='#B2C248',
    method='ywm'
)
plt.show()
```

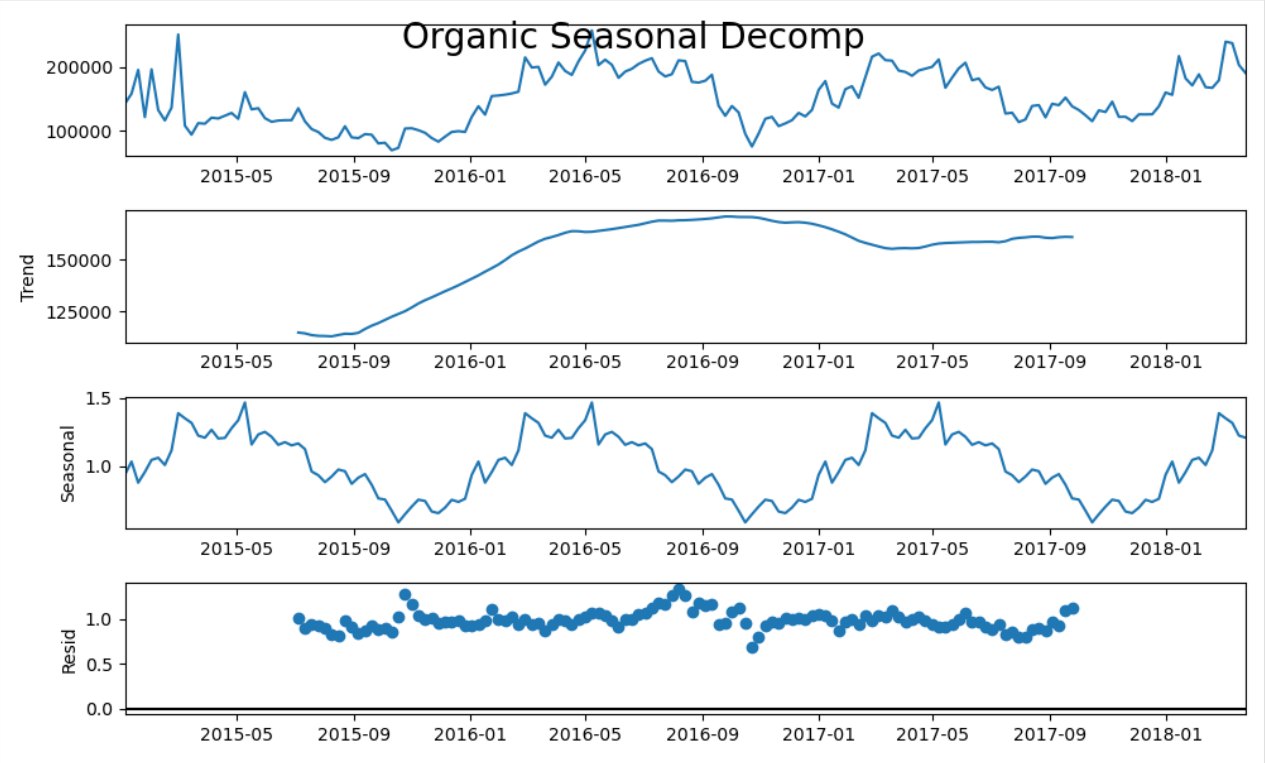


14.2.5 Seasonal Decomposition Plots

[10]:
```
plt.rc("figure",figsize=(10,6))
fcon.seasonal_decompose(model='mul').plot()
plt.suptitle('Conventional Seasonal Decomp',size=20)
plt.show()
```



[11]:
```
forg.seasonal_decompose(model='mul').plot()
plt.suptitle('Organic Seasonal Decomp',size=20)
plt.show()
```



14.2.6 Check Stationarity

[12]:
```
critical_pval = 0.05
print('-'*100)
print('Conventional Augmented Dickey-Fuller results:')
stat, pval, _, _, _, _ = fcon.adf_test(full_res=True)
print('the test-stat value is: {:.2f}'.format(stat))
print('the p-value is {:.4f}'.format(pval))
print('the series is {}'.format('stationary' if pval < critical_pval else 'not stationary
↪'))
print('-'*100)
print('Organic Augmented Dickey-Fuller results:')
stat, pval, _, _, _, _ = forg.adf_test(full_res=True)
print('the test-stat value is: {:.2f}'.format(stat))
print('the p-value is {:.4f}'.format(pval))
print('the series is {}'.format('stationary' if pval < critical_pval else 'not stationary
↪'))
print('-'*100)
```

```
----------------------------------------------------------------------------------------------------
↪-----------
Conventional Augmented Dickey-Fuller results:
the test-stat value is: -3.35
the p-value is 0.0128
the series is stationary
----------------------------------------------------------------------------------------------------
↪-----------
Organic Augmented Dickey-Fuller results:
the test-stat value is: -2.94
the p-value is 0.0404
the series is stationary
----------------------------------------------------------------------------------------------------
↪-----------
```

14.3 Scalecast - Univariate

14.3.1 Load Objects with Xvars:

- Find best combination of trend, lags, and seasonality monitoring the validation set (4 observations before the test set)

[13]:
```
for f in (fcon,forg):
    f.auto_Xvar_select(
        estimator = 'elasticnet',
        monitor = 'ValidationMetricValue',
        irr_cycles = [26], # try irregular semi-annual seaosnality
        cross_validate=True,
        cvkwargs={
            'k':3,
            'test_length':13,
            'space_between_sets':4,
```

(continues on next page)

(continued from previous page)

```
        }
    )
    print(f)
```

14       xgboost       Organic   37617.5747    -0.2571        0.6991
15           gbt       Organic   40632.6313    -0.4667     7511.2968

    InSampleR2  best_model
0       1.0000        True
1       0.5510       False
2       0.6133       False
3       0.6813       False
4       0.9747       False
5       0.1218       False
6      -0.0000       False
7      -0.0049       False
8       0.2451        True
9       0.8699       False
10      0.8967       False
11     -0.0000       False
12      0.8951       False
13      0.9483       False
14      1.0000       False
15      0.9689       False
```

Because running so many models can cause overfitting on the test set, we can check the average test error between all models to get another metric of how effective our modeling process is.

[23]:
```
print('-'*100)
for series in ms['Series'].unique():
    print('univariate average test MAPE for {}: {:.4f}'.format(series,ms.loc[ms['Series
↪'] == series,'TestSetRMSE'].mean()))
    print('univariate average test R2 for {}: {:.2f}'.format(series,ms.loc[ms['Series']␣
↪== series,'TestSetR2'].mean()))
    print('-'*100)
```

```
----------------------------------------------------------------------------------------------------
↪-----------
univariate average test MAPE for Conventional: 1244529.1652
univariate average test R2 for Conventional: 0.14
----------------------------------------------------------------------------------------------------
↪-----------
univariate average test MAPE for Organic: 34857.0573
univariate average test R2 for Organic: -0.09
----------------------------------------------------------------------------------------------------
↪-----------
```

These are interesting error metrics, but a lot of models, including XGBoost and GBT appear to be overfitting. Let's see if we can beat the results with a multivariate approach.

14.4 Scalecast - Multivariate

14.4.1 Set MV Parameters

- Forecast horizon already set
- Xvars already set
- Test size must be set: 20%
- Validation size must be set: 4 periods

[24]:
```
mvf = MVForecaster(
    fcon,forg,
    names=['Conventional','Organic'],
    test_length = .2,
    valiation_length = 4,
    cis = True,
    metrics = ['rmse','r2'],
) # init the mvf object
mvf
```

[24]:
```
MVForecaster(
    DateStartActuals=2015-01-04T00:00:00.000000000
    DateEndActuals=2018-03-25T00:00:00.000000000
    Freq=W-SUN
    N_actuals=169
    N_series=2
    SeriesNames=['Conventional', 'Organic']
    ForecastLength=52
    Xvars=['weeksin', 'weekcos', 'monthsin', 'monthcos', 'quartersin', 'quartercos', 'lnt
↪']
    TestLength=33
    ValidationLength=1
    ValidationMetric=rmse
    ForecastsEvaluated=[]
    CILevel=0.95
    CurrentEstimator=mlr
    OptimizeOn=mean
    GridsFile=MVGrids
)
```

The lags from each Forecaster object dropped but they will be added into the multivariate models differently.

14.4.2 View Series Correlation

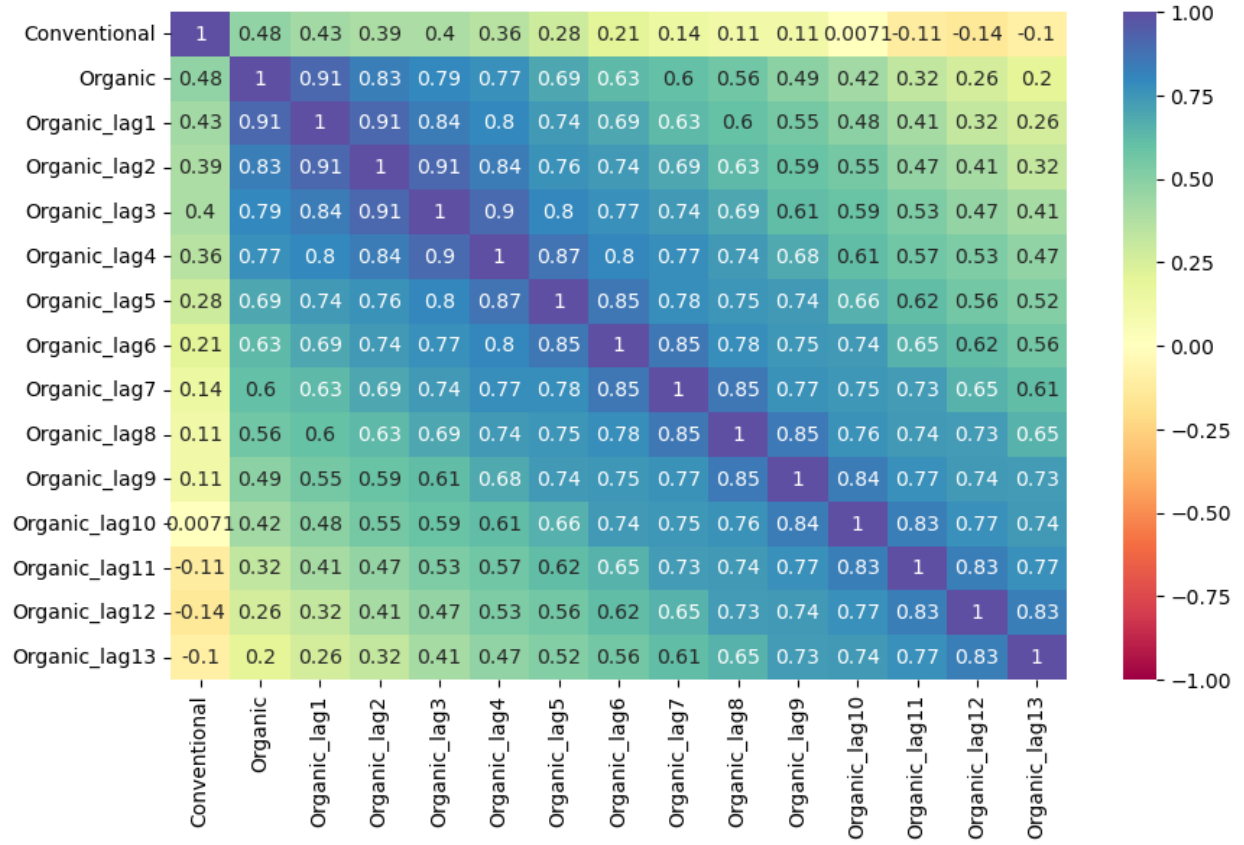
[25]:
```
mvf.corr()
```

[25]:

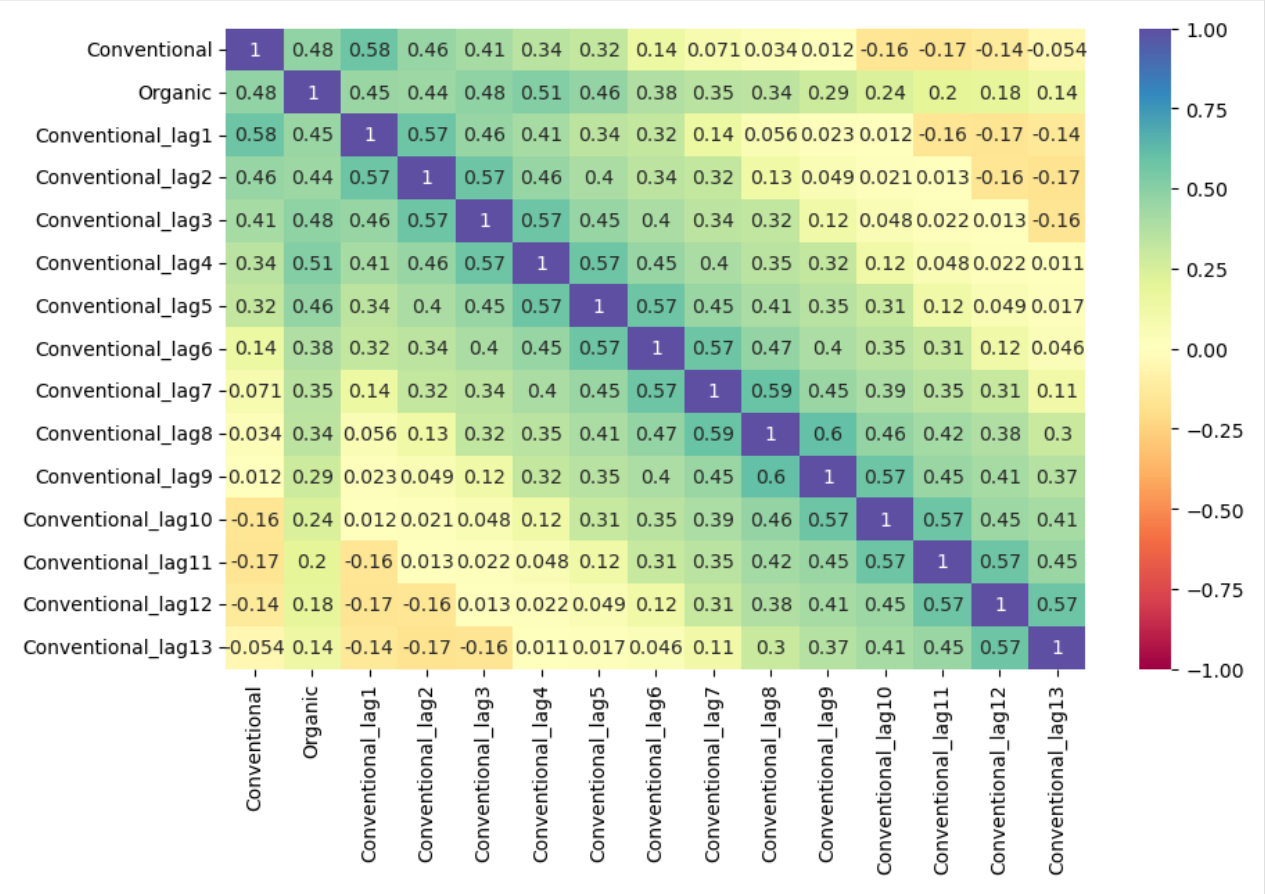
	Conventional	Organic
Conventional	1.0000	0.4802
Organic	0.4802	1.0000

14.4.3 View Series Correlation with each others' lags

[26]:
```
mvf.corr_lags(
    y='Conventional',
    x='Organic',
    lags=13,
    disp='heatmap',
    annot=True,
    vmin=-1,
    vmax=1,
    cmap = 'Spectral',
)
plt.show()
```



[27]:
```
mvf.corr_lags(
    y='Organic',
    x='Conventional',
    lags=13,
    disp='heatmap',
    annot=True,
    vmin=-1,
    vmax=1,
    cmap = 'Spectral',
)
plt.show()
```



14.4.4 Set Optimize On

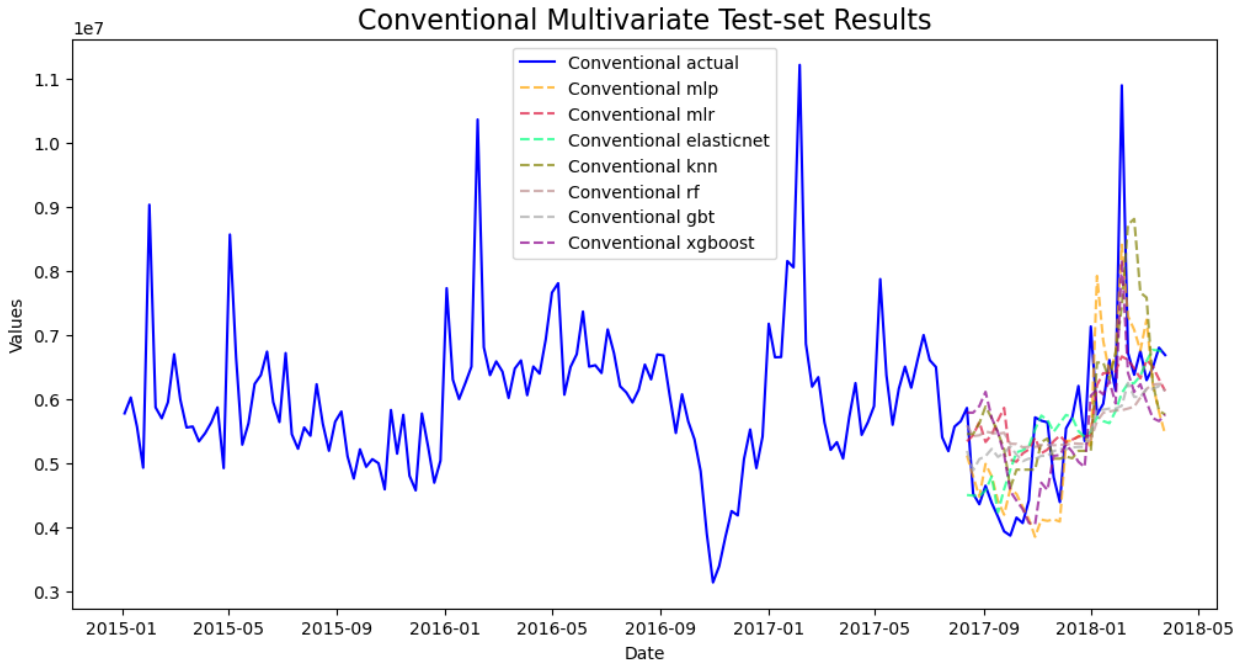
- If predicting one series is more important than predicting the other, you can use this code to let the code know to favor one over the other
- By default, it uses the mean error metrics between all series

[28]:
```
# how to optimize on one series
mvf.set_optimize_on('Organic')
# how to optimize using a weighted avarage
mvf.add_optimizer_func(lambda x: x[0]*.25 + x[1]*.75,'weighted')
mvf.set_optimize_on('weighted')
# how to optimize on the average of both/all series (default)
mvf.set_optimize_on('mean')
```

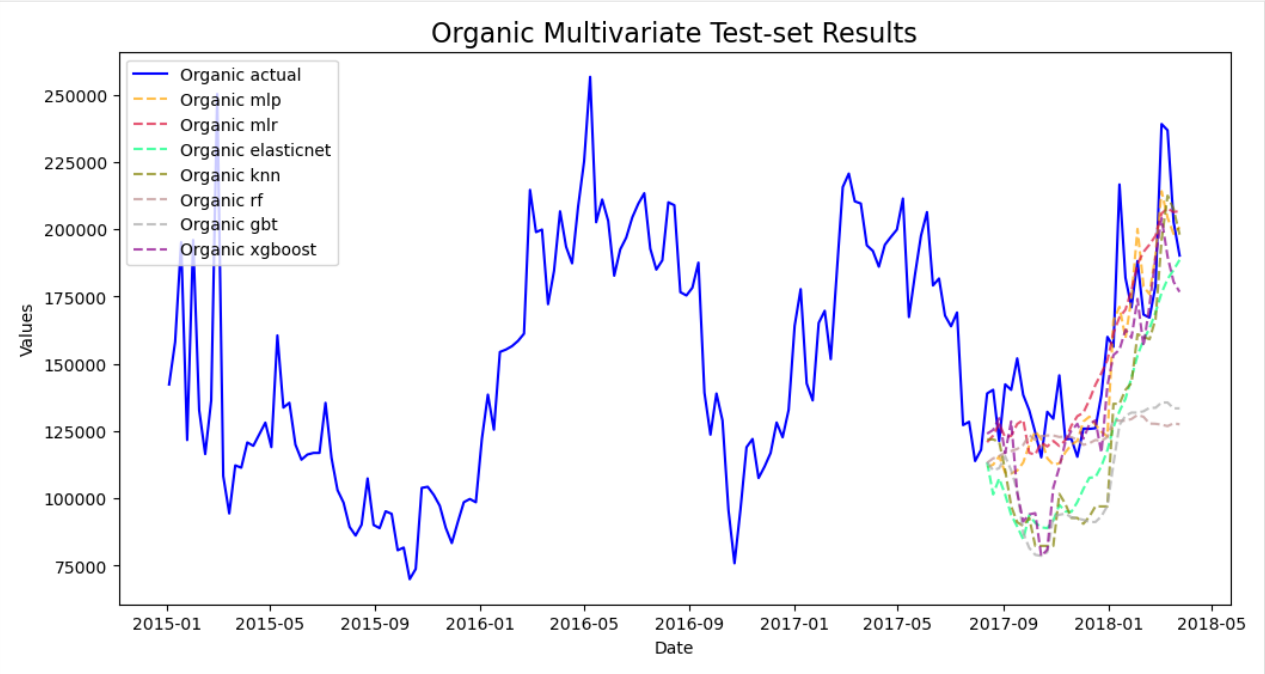
14.4.5 Tune and Test with Selected Models

[29]:
```
mvf.tune_test_forecast(models)
mvf.set_best_model(determine_best_by='TestSetRMSE')
```

[30]:
```
# not plotting both series at the same time because they have significantly different␣
↪scales
mvf.plot_test_set(series='Conventional',put_best_on_top=True)
plt.title('Conventional Multivariate Test-set Results',size=16)
plt.show()
```



[31]:
```
mvf.plot_test_set(series='Organic',put_best_on_top=True)
plt.title('Organic Multivariate Test-set Results',size=16)
plt.show()
```



14.4.6 Export Model Summaries

[32]:
```
pd.options.display.max_colwidth = 100
results = mvf.export('model_summaries')
results[
    [
        'ModelNickname',
        'Series',
        'HyperParams',
        'TestSetRMSE',
        'TestSetR2',
        'InSampleRMSE',
        'InSampleR2',
        'Lags'
    ]
]
```

[32]:
```
   ModelNickname        Series  \
0            mlp  Conventional
1            mlr  Conventional
2     elasticnet  Conventional
3            knn  Conventional
4             rf  Conventional
5            gbt  Conventional

14.4.8 Plot Final Forecasts

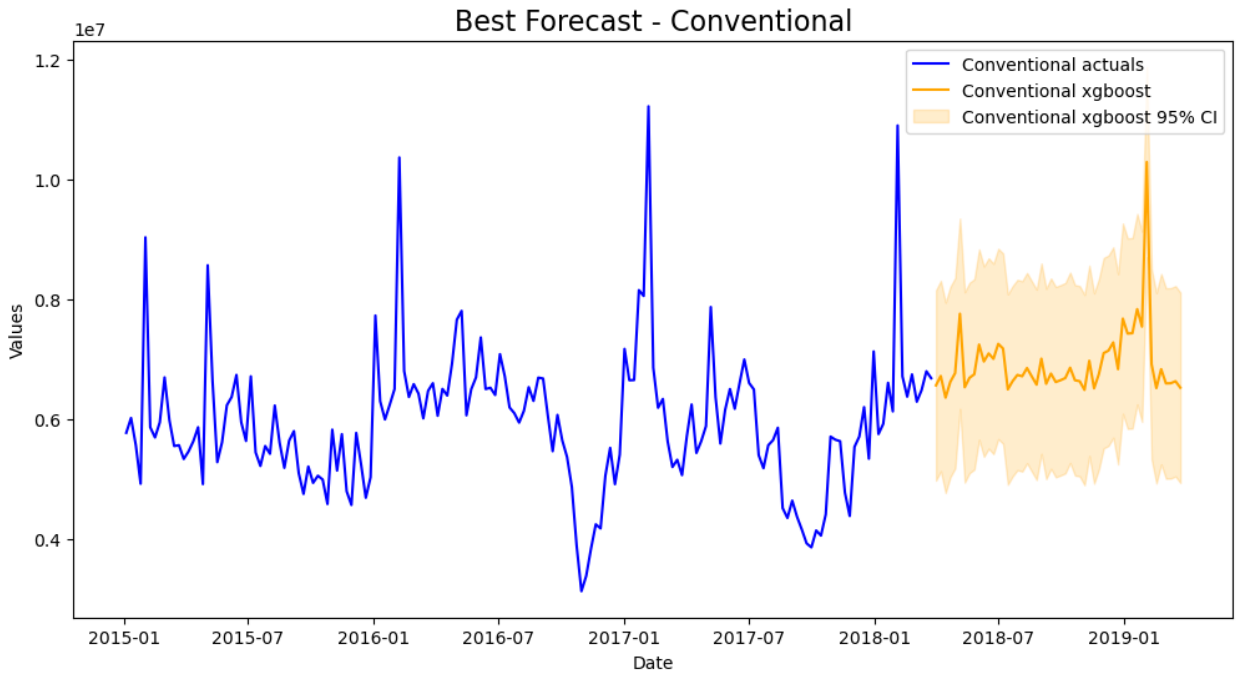
[39]:
```
best_model_con = (
    results2.loc[results2['Series'] == 'Conventional']
    .sort_values('TestSetR2',ascending=False)
    .iloc[0,0]
)
```

[40]:
```
mvf.plot(series='Conventional',models=best_model_con,ci=True)
```

(continues on next page)

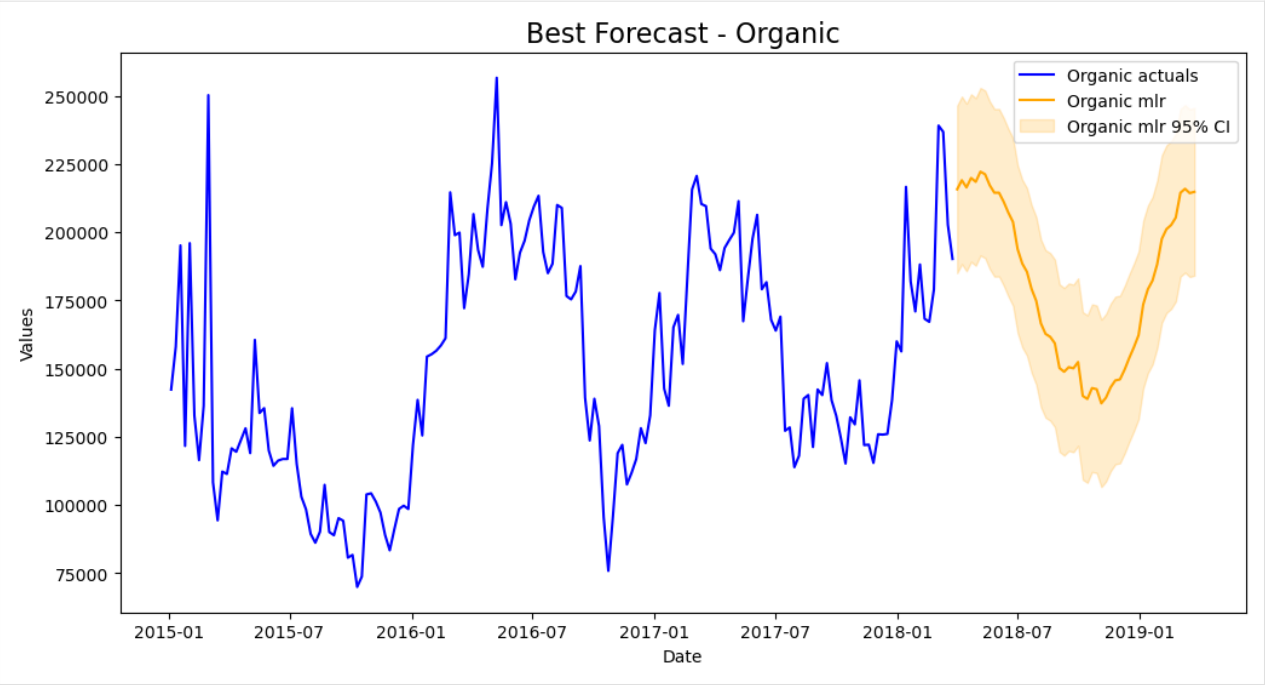
(continued from previous page)

```
plt.title('Best Forecast - Conventional',size=16)
plt.show()
```



[41]:
```
best_model_org = (
    results2.loc[results2['Series'] == 'Organic']
    .sort_values('TestSetR2',ascending=False)
    .iloc[0,0]
)
```

[42]:
```
mvf.plot(series='Organic',models=best_model_org,ci=True)
plt.title('Best Forecast - Organic',size=16)
plt.show()
```



All-in-all, better results on the test-set were obtained by using the multivariate approach.

14.5 Multivariate Backtest

Just like in univariate modeling, we can evaluate the results of this modeling approach using backtesting.

[46]:
```
from scalecast.Pipeline import Transformer, Reverter, MVPipeline
from scalecast.util import backtest_metrics

def mvforecaster(mvf):
    mvf.add_seasonal_regressors('month','quarter',raw=False,sincos=True)
    mvf.tune_test_forecast(
        models=[best_model_con,best_model_org],
    )

pipeline = MVPipeline(
    steps = [('Forecast',mvforecaster)],
    validation_length = 4,
)
```

[47]:
```
backtest_results = pipeline.backtest(
    fcon,
    forg,
    cis=False,
    test_length = 0,
    fcst_length = 52,
    jump_back = 4,
    n_iter = 3,
)
```

[48]:
```
backtest_metrics(
    backtest_results,

CHAPTER

FIFTEEN

MULTIVARIATE - BEYOND THE BASICS

This notebook shows multivariate forecasting procedures with scalecast. It requires `0.18.2`. It uses the Avocados dataset.

We will treat this like a demand forecasting problem. We want to know how many total Avocados will be in demand in the next quarter. But since we know demand and price are intricately related, we will use the historical Avocado prices as a predictor of demand.

[1]:
```
import pandas as pd
import numpy as np
from scalecast.Forecaster import Forecaster
from scalecast.MVForecaster import MVForecaster
from scalecast.Pipeline import MVPipeline
from scalecast.util import (
    find_optimal_transformation,
    find_optimal_lag_order,
    break_mv_forecaster,
    backtest_metrics,
    backtest_for_resid_matrix,
    get_backtest_resid_matrix,
    overwrite_forecast_intervals,
)
from scalecast import GridGenerator
```

Read in hyperparameter grids for optimizing models.

[2]:
```
GridGenerator.get_example_grids()
GridGenerator.get_mv_grids()
```

[3]:
```
pd.options.display.max_colwidth = 100
pd.options.display.float_format = '{:,.2f}'.format
```

[4]:
```
# arguments to pass to every Forecaster/MVForecaster object we create
Forecaster_kws = dict(
    test_length = 13,
    validation_length = 13,
    metrics = ['rmse','r2'],
)
```

[5]:
```
# model summary columns to export everytime we check a model's performance
export_cols = ['ModelNickname','HyperParams','TestSetR2','TestSetRMSE']
```

[6]:
```
# read data
data = pd.read_csv('avocado.csv',parse_dates=['Date']).sort_values(['Date'])
# sort appropriately (not doing this could cause issues)
data = data.sort_values(['region','type','Date'])

data.head()
```

    CurrentEstimator=mlr
    OptimizeOn=mean
    GridsFile=MVGrids
)
```

15.1 1. Transformations

To make the forecasting task easier, we can transform the data in each Forecaster object before feeding them to the MVForecaster object. The below function will search through many transformations, using out-of-sample testing to score each one. We pass four possible seasonalities to the function (monthly, quarterly, bi-annually, annually) and the results are several seasonal adjustments get selected.

[13]:
```
transformers = []
reverters = []

for name, f in zip(('volume','price'),(fvol,fprice)):
    print(f'\nFinding best transformation for the {name} series.')
    transformer, reverter = find_optimal_transformation(
        f,
        m = [
            4,
            13,
            26,
            52,
        ],
        test_length = 13,
```

(continues on next page)

(continued from previous page)

```
        num_test_sets = 2,
        space_between_sets = 13,
        return_train_only = True,
        verbose = True,
    )
    transformers.append(transformer)
    reverters.append(reverter)
```

```
Finding best transformation for the volume series.
Using mlr model to find the best transformation set on 2 test sets, each 13 in length.
All transformation tries will be evaluated with 4 lags.

```

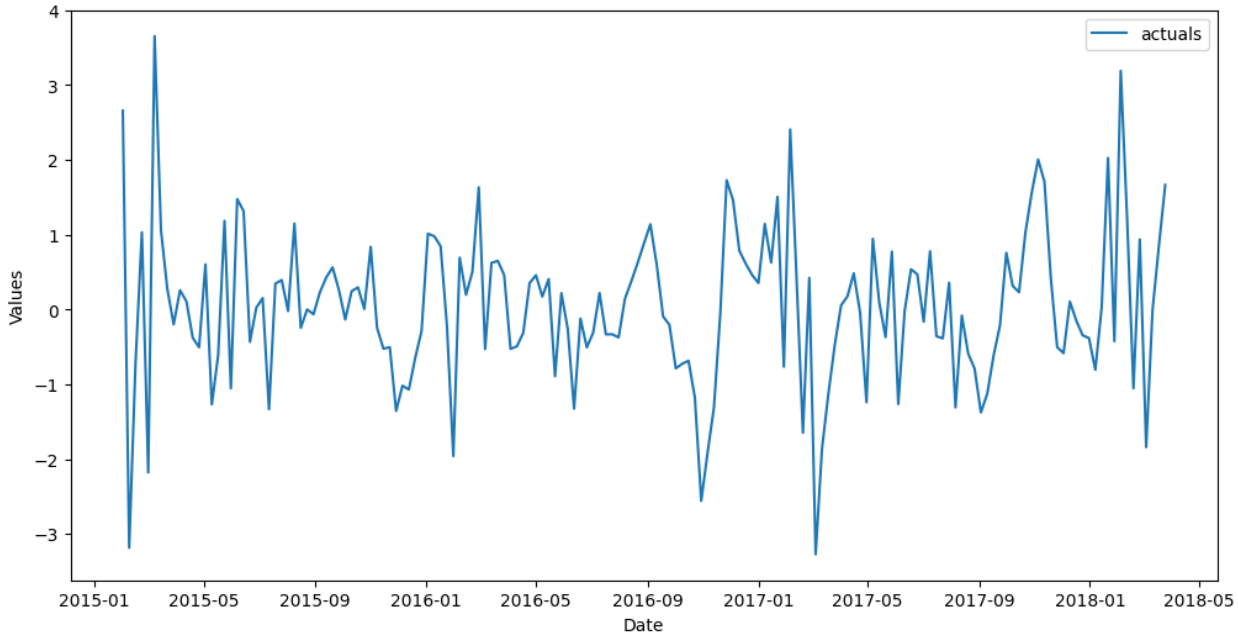
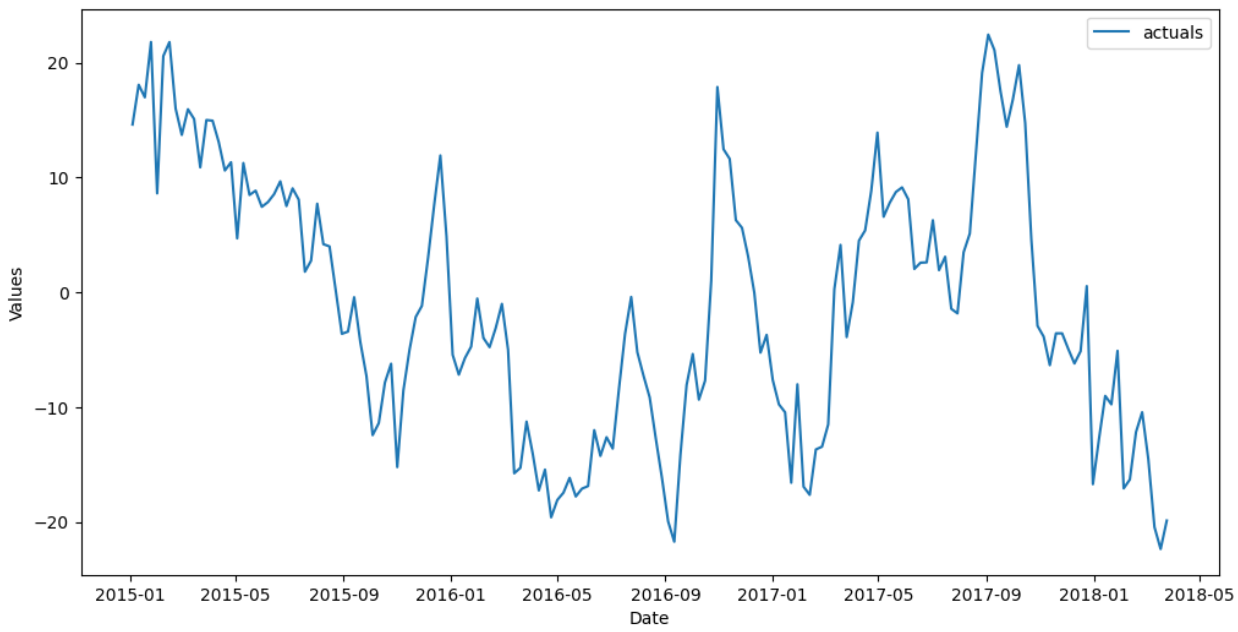
Plot the series after a transformation has been taken.

[14]:
```
fvol1 = transformers[0].fit_transform(fvol)
fvol1.plot();
```



[15]:
```
fprice1 = transformers[1].fit_transform(fprice)
fprice1.plot();
```



Now, combine into an `MVForecaster` object.

[16]:
```
mvf1 = MVForecaster(
    fvol1,
    fprice1,
    names = ['volume','price'],
    **Forecaster_kws,
)
```

15.2 2. Optimal Lag Selection

15.2.1 Method 1: Univariate out-of-sample testing

- The functions below choose the best lags based on what minimizes RMSE on an out-of-sample validation set.

[17]:
```
fvol1.auto_Xvar_select(try_trend=False,try_seasonalities=False)
fvol1.get_regressor_names()
```

[17]:
```
['AR1',
 'AR2',
 'AR3',
 'AR4',
 'AR5',
 'AR6',
 'AR7',
 'AR8',
 'AR9',
 'AR10',
 'AR11',
 'AR12',
 'AR13']
```

[18]:
```
fprice1.auto_Xvar_select(try_trend=False,try_seasonalities=False)
fprice1.get_regressor_names()
```

[18]:
```
['AR1', 'AR2', 'AR3', 'AR4', 'AR5', 'AR6', 'AR7', 'AR8', 'AR9', 'AR10', 'AR11']
```

15.2.2 Method 2: Information Criteria Search with VAR

[19]:
```
lag_order_res = find_optimal_lag_order(mvf1,train_only=True)
lag_orders = pd.DataFrame({
    'aic':[lag_order_res.aic],
    'bic':[lag_order_res.bic],
})

lag_orders
```

[19]:
```
   aic  bic
0   12    4
```

15.2.3 Method 3: Multivariate Cross Validation with MLR

[20]:
```
lags = [
    1,
    2,
    3,
    4,
    9,
    10,
```

(continues on next page)

(continued from previous page)

```
    11,
    12,
    13,
    {'volume':13,'price':9},
    [4,9,12,13],
]
```

[21]:
```
grid = dict(
    lags = lags
)
```

[22]:
```
mvf1.set_optimize_on('volume')
```

[23]:
```
mvf1.ingest_grid(grid)
mvf1.cross_validate(k=3,test_length=13,verbose = True,dynamic_tuning=True)
```

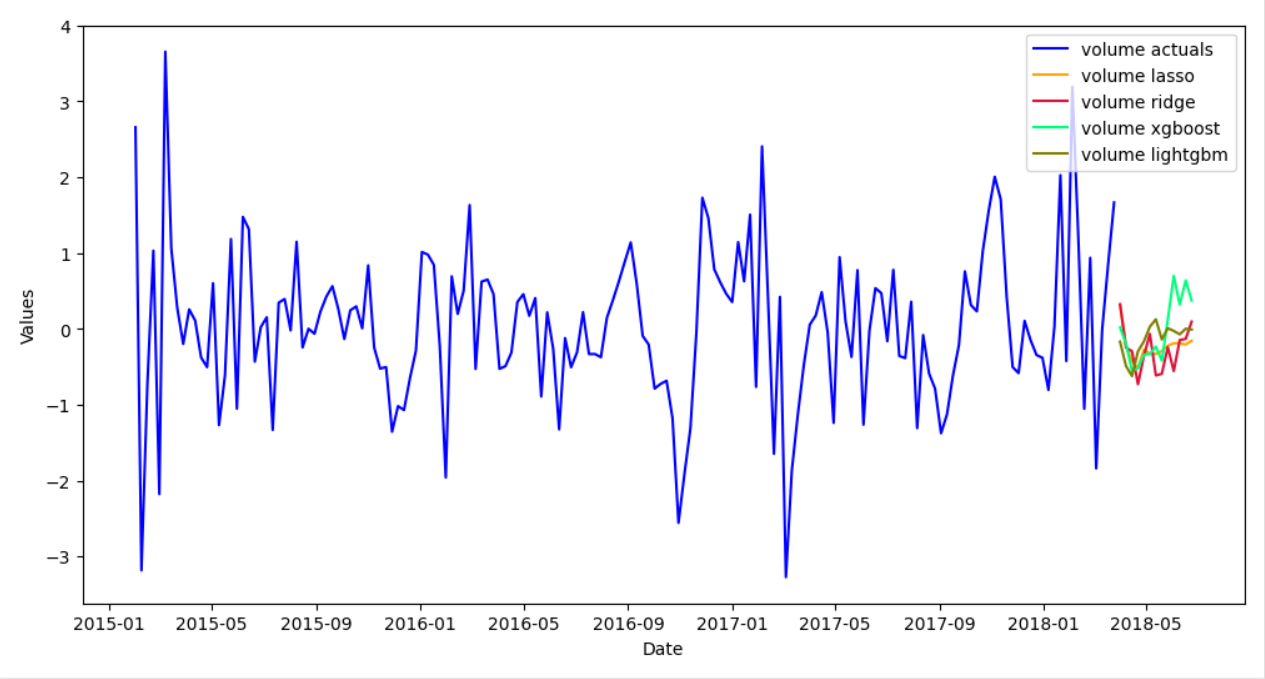
```
Num hyperparams to try for the mlr model: 11.
Fold 0: Train size: 139 (2015-02-01 00:00:00 - 2017-09-24 00:00:00). Test Size: 13 (2017-
↪10-01 00:00:00 - 2017-12-24 00:00:00).
Fold 1: Train size: 126 (2015-02-01 00:00:00 - 2017-06-25 00:00:00). Test Size: 13 (2017-
↪07-02 00:00:00 - 2017-09-24 00:00:00).
Fold 2: Train size: 113 (2015-02-01 00:00:00 - 2017-03-26 00:00:00). Test Size: 13 (2017-
↪04-02 00:00:00 - 2017-06-25 00:00:00).
Chosen paramaters: {'lags': 10}.
```

15.3 3. Model Optimization with Cross Validation

[24]:
```
def forecaster(mvf):
    mvf.tune_test_forecast(
        ['lasso','ridge','xgboost','lightgbm'],
        cross_validate = True,
        k = 3,
        test_length = 13,
        dynamic_tuning=True,
        limit_grid_size=.2,
        min_grid_size=4,
    )

forecaster(mvf1)
```

[25]:
```
mvf1.plot(series='volume');
```



[26]:
```
mvf1.export('model_summaries',series='volume')[['Series'] + export_cols + ['Lags']].
↪style.set_properties(height = 5)
```

[26]:
```
<pandas.io.formats.style.Styler at 0x22789064880>
```

[27]:
```
mvf1
```

[27]:

CHAPTER

SIXTEEN

RNN AND LSTM

This notebook demonstrates the capabilities of the RNN model in scalecast.

- Download data: https://www.kaggle.com/robervalt/sunspots
- Requirements for this notebook:
- `pip install tensorflow`
- `!pip install tqdm`
- `!pip install ipython`
- `!pip install ipywidgets`
- `!jupyter nbextension enable --py widgetsnbextension`
- if using Jupyter Lab: `!jupyter labextension install @jupyter-widgets/jupyterlab-manager`

[1]:
```
import pandas as pd
import numpy as np
import pandas_datareader as pdr
import matplotlib
import matplotlib.pyplot as plt
import seaborn as sns
from tqdm.notebook import tqdm
from dateutil.relativedelta import relativedelta
from scalecast.Forecaster import Forecaster
```

[2]:
```
df = pd.read_csv('Sunspots.csv',index_col=0,names=['Date','Target'],header=0)
f = Forecaster(
    y=df['Target'],
    current_dates=df['Date'],
    test_length = 240,
    future_dates = 240,
    cis = True,
)
f
```

[2]:
```
Forecaster(
    DateStartActuals=1749-01-31T00:00:00.000000000
    DateEndActuals=2021-01-31T00:00:00.000000000
    Freq=M
    N_actuals=3265
    ForecastLength=240
    Xvars=[]
```

(continues on next page)

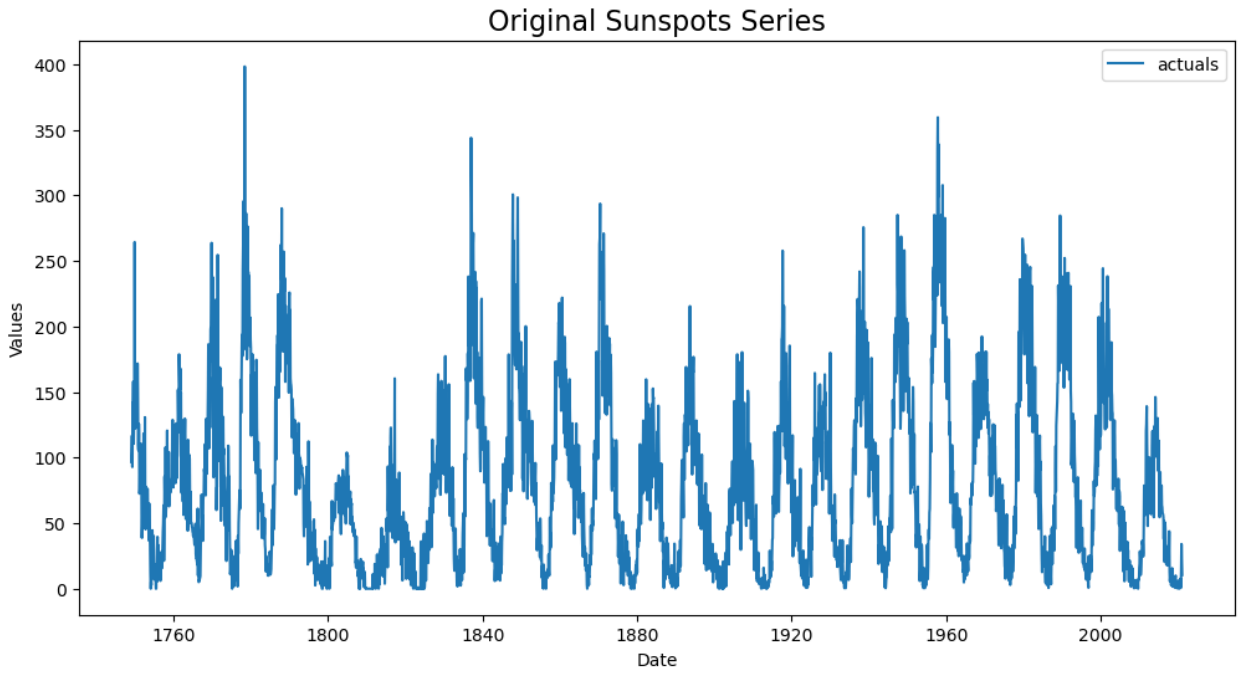
(continued from previous page)

```
    TestLength=240
    ValidationMetric=rmse
    ForecastsEvaluated=[]
    CILevel=0.95
    CurrentEstimator=mlr
    GridsFile=Grids
)
```

16.1 EDA

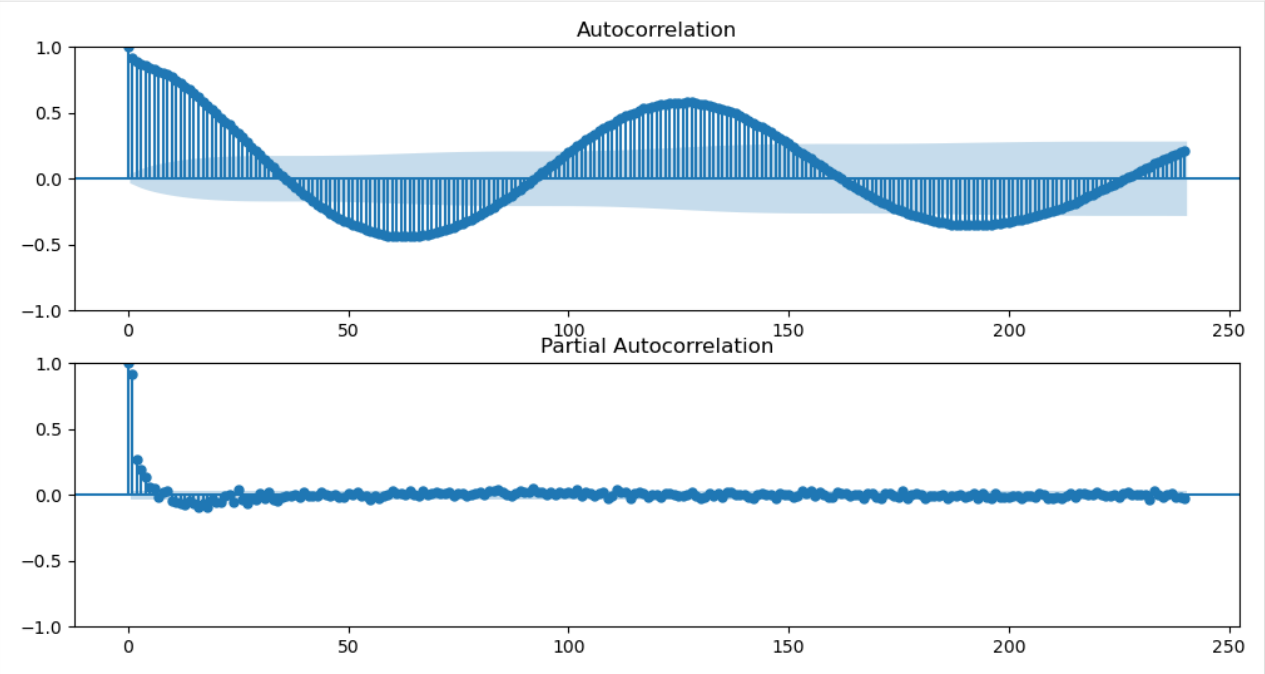
[3]:
```
f.plot()
plt.title('Original Sunspots Series',size=16)
```

[3]:
```
Text(0.5, 1.0, 'Original Sunspots Series')
```



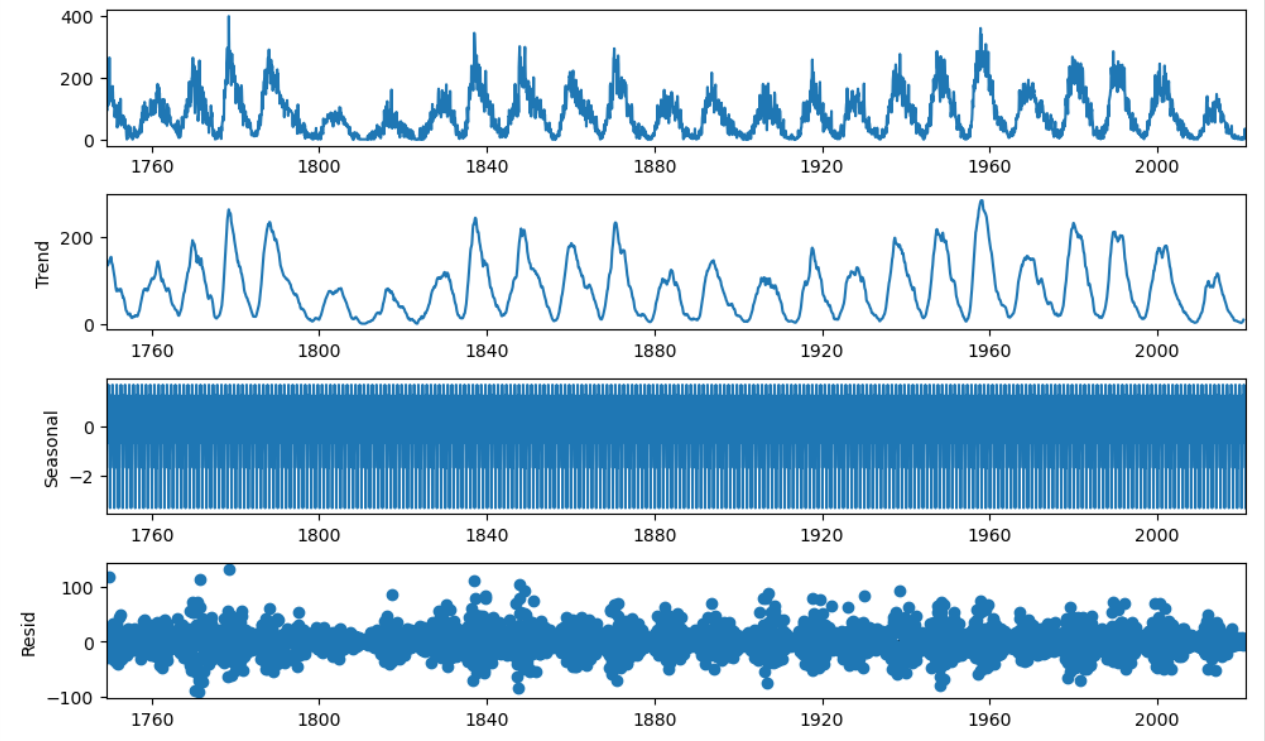
Let's see the ACF and PACF plots, allowing 240 lags to see this series' irregular 10-year cycle.

[4]:
```
figs, axs = plt.subplots(2, 1, figsize = (12,6))
f.plot_acf(ax=axs[0],lags=240)
f.plot_pacf(ax=axs[1],lags=240,method='ywm')
plt.show()
```



Let's view the series' seasonal decomposition.

[5]:
```
plt.rc("figure",figsize=(10,6))
f.seasonal_decompose().plot()
plt.show()
```



It is very difficult to make out anything useful from this graph.

16.2 Forecast RNN Model

- See Darts' GRU on the same series: https://unit8co.github.io/darts/examples/04-RNN-examples.html?highlight=sunspots

16.2.1 SimpleRNN

16.2.1.1 Unlayered model

- 1 hidden layer with 20% dropout
- 25 epochs
- 20% validcation split
- 32 batch size
- Tanh activation
- Adam optimizer
- MAE loss function

[6]:
```
f.auto_Xvar_select(
    try_trend = False,
    irr_cycles = [120,132,144],
    cross_validate = True,
    cvkwargs = {'k':3},
    dynamic_tuning = 240,
)
f.set_estimator('rnn')
f
```

```
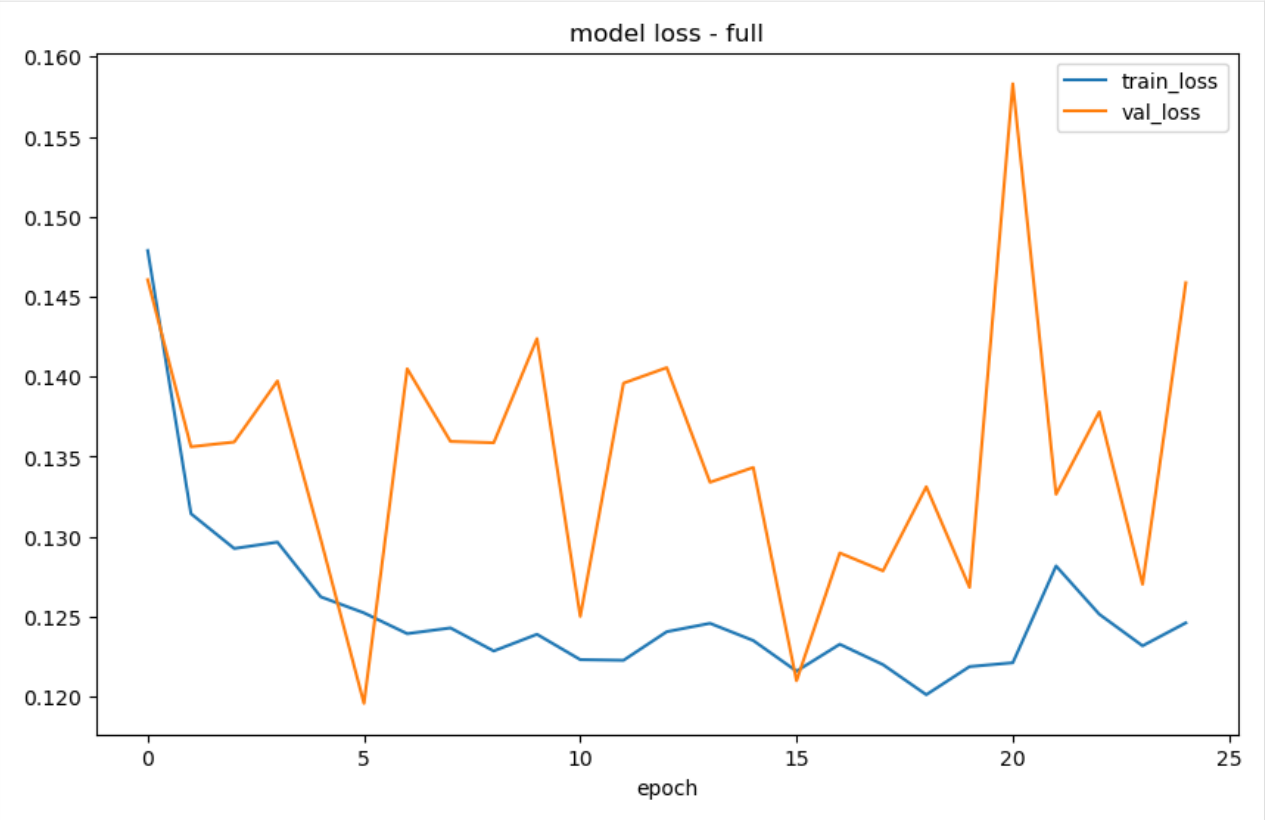
1/1 [==============================] - 0s 91ms/step
88/88 [==============================] - 1s 10ms/step
```

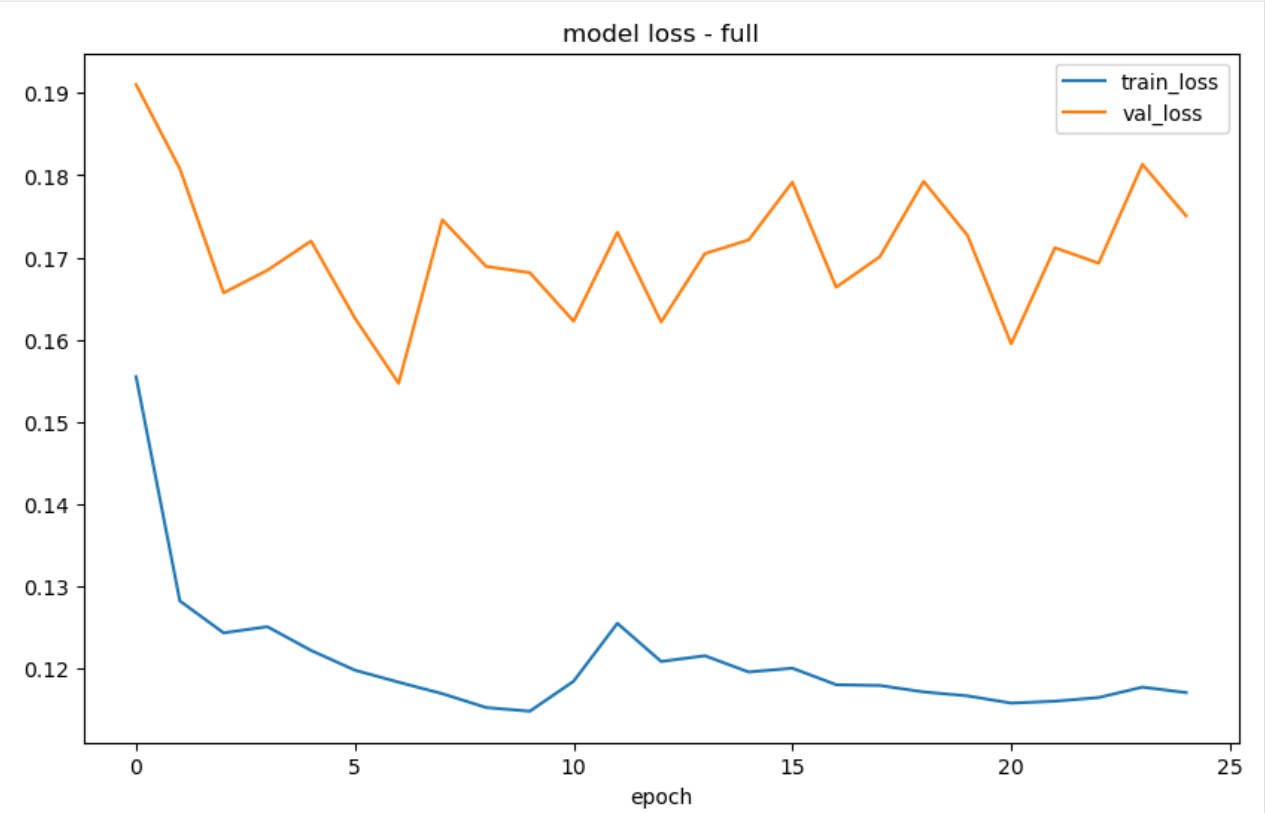


16.2.1.2 Layered Model

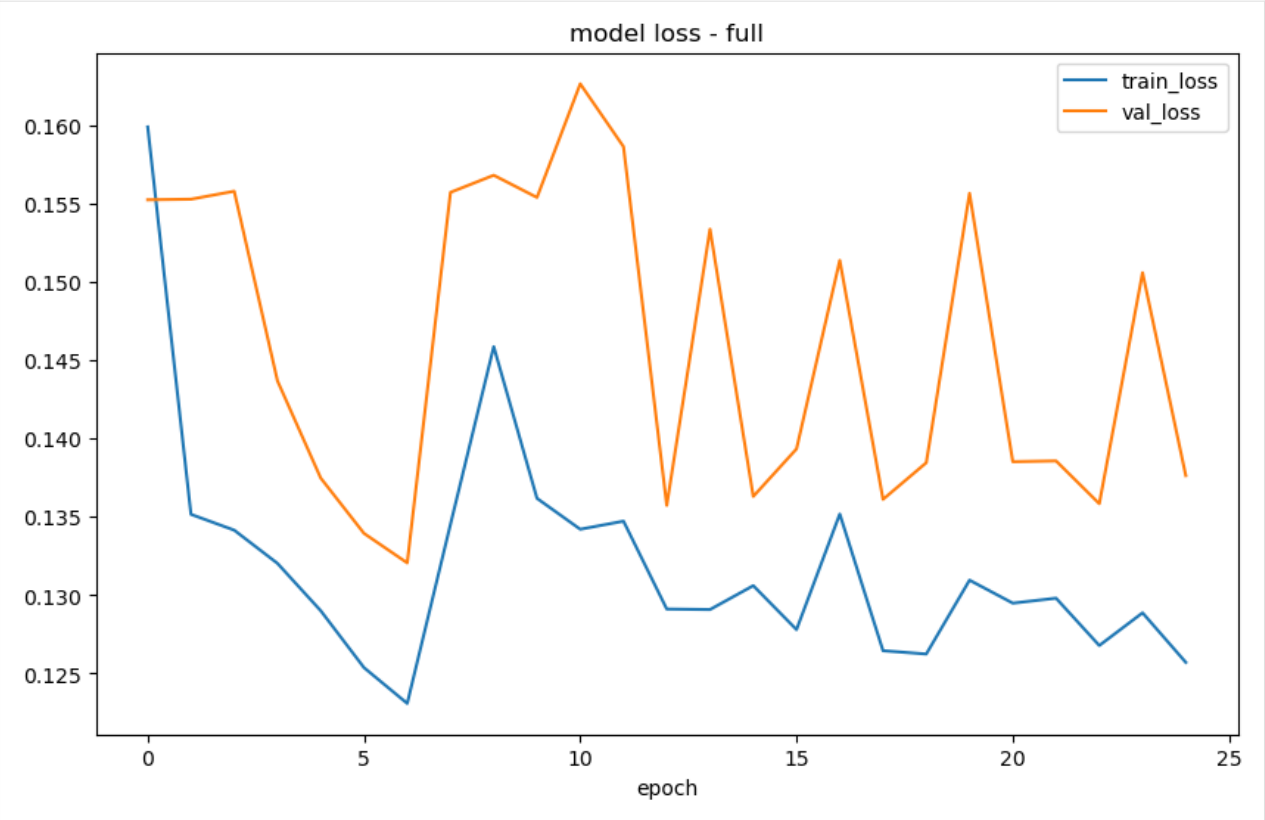
- 2 SimpleRNN layers, 100 units each
- 2 Dense layers, 10 units each
- No dropout
- Everything else the same

[8]:
```
f.manual_forecast(
    layers_struct=[
        ('SimpleRNN',{'units':100,'dropout':0})
    ] * 2 + [
        ('Dense',{'units':10})
    ]*2,
    epochs=25,
    random_seed=42,
    plot_loss=True,
    validation_split=0.2,
    call_me='rnn_layered',
    verbose=0
)
```

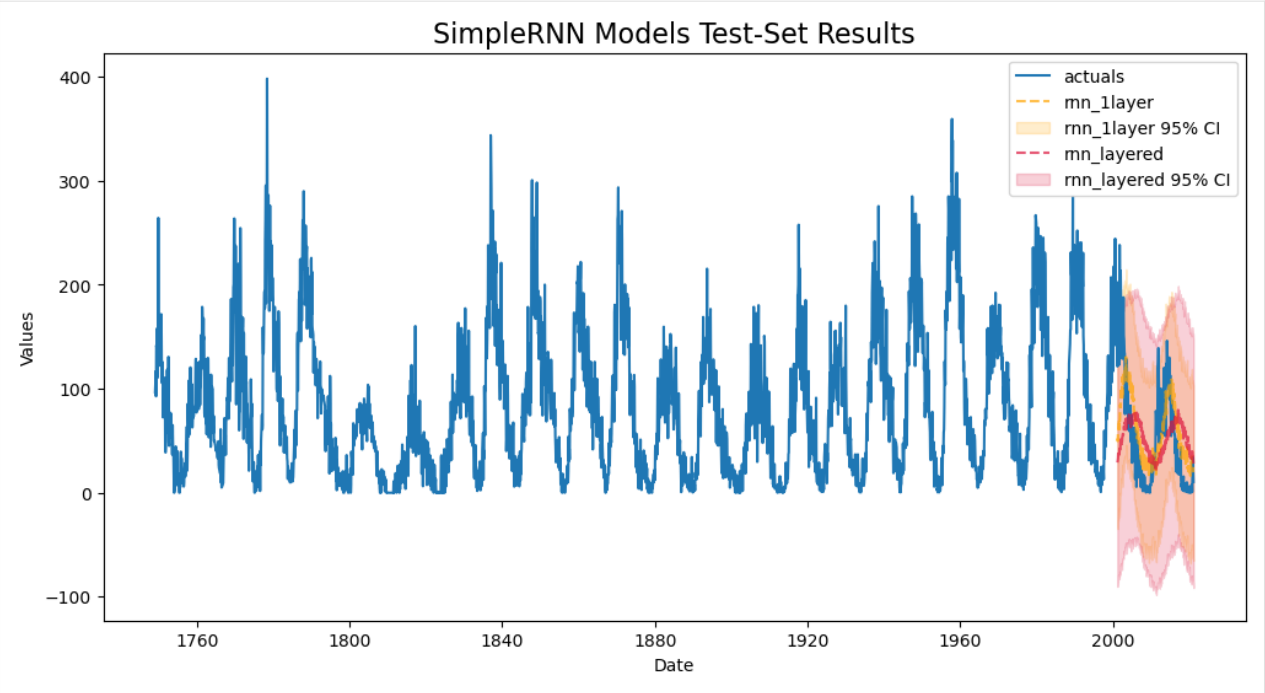
```
1/1 [==============================] - 0s 150ms/step
```



```
1/1 [==============================] - 0s 154ms/step
88/88 [==============================] - 2s 19ms/step
```



[9]:
```
f.plot_test_set(
    ci=True,
    models=['rnn_1layer','rnn_layered'],
    order_by='TestSetRMSE',
)
plt.title('SimpleRNN Models Test-Set Results',size=16)
plt.show()
```



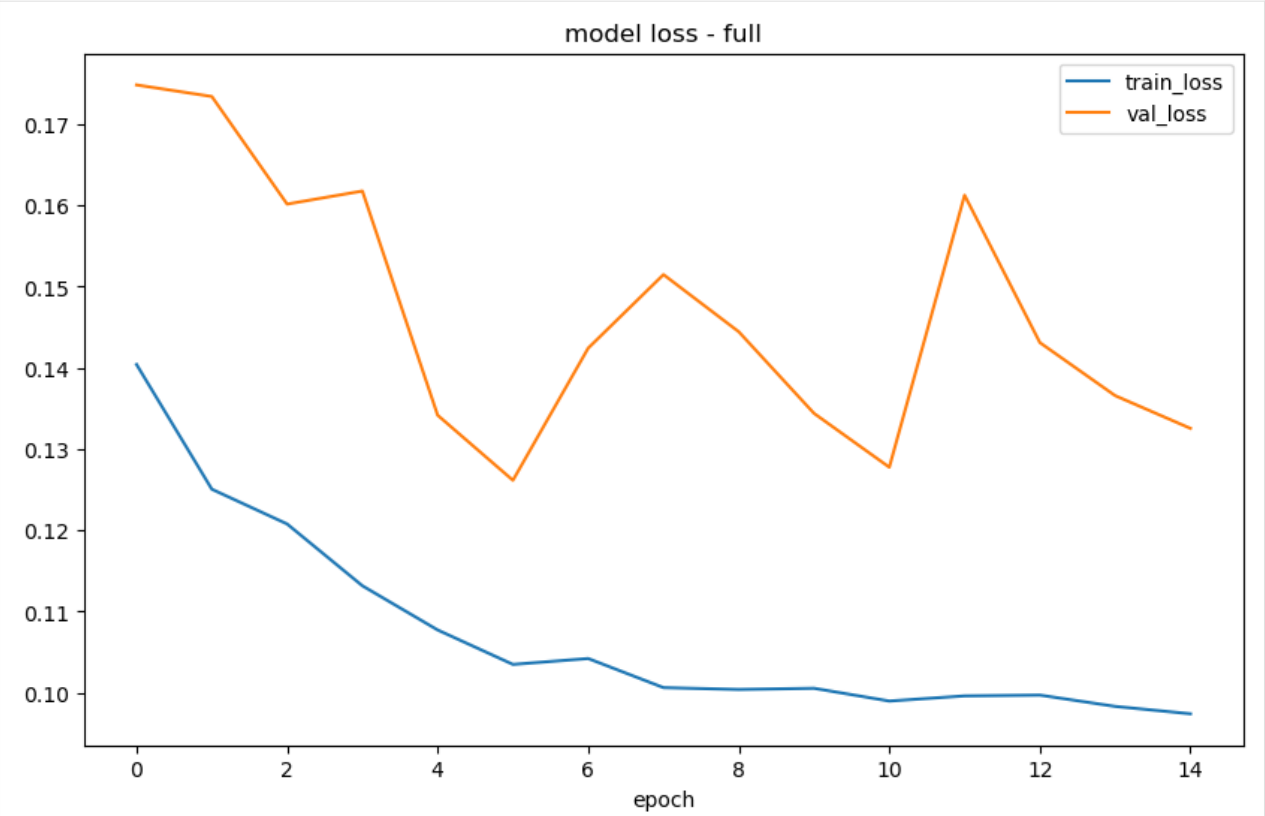
16.2.2 LSTM

16.2.2.1 Unlayered Model

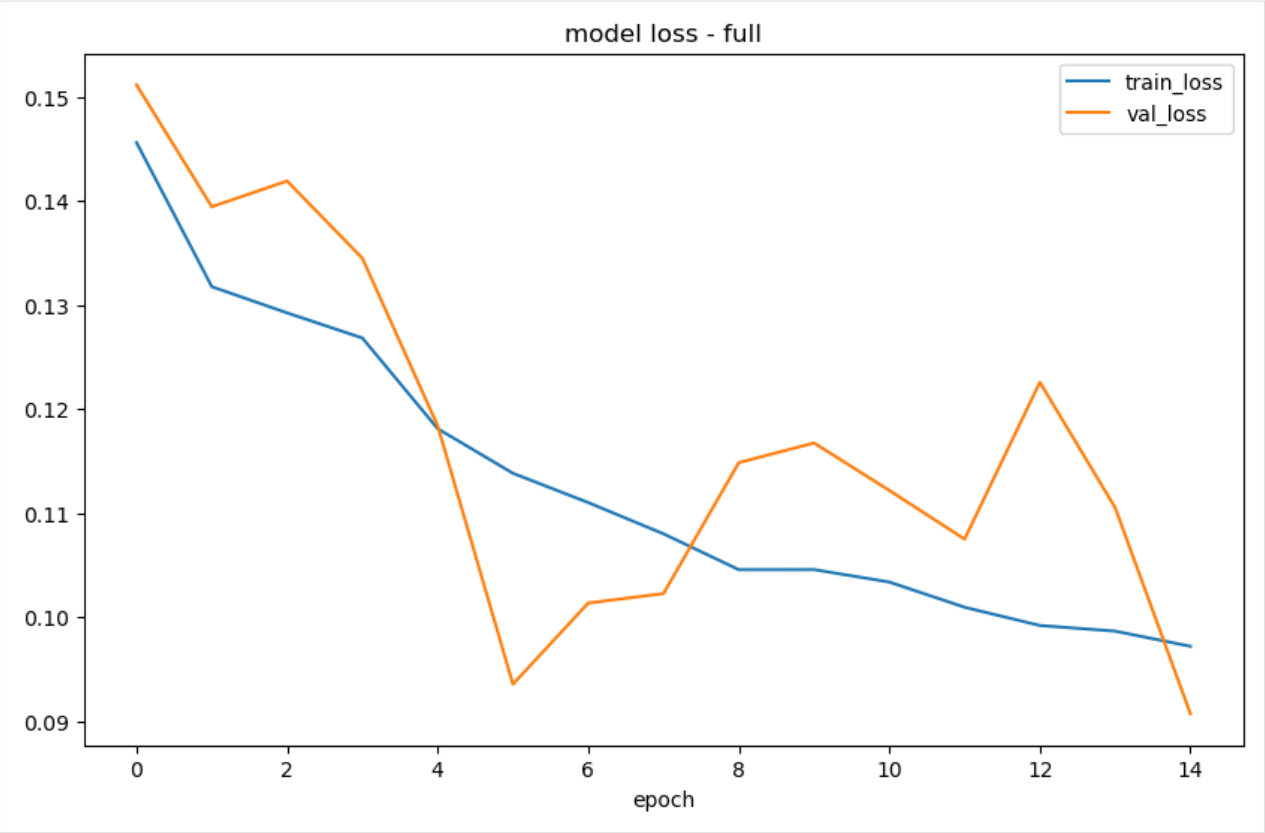
- One LSTM layer with 20% dropout
- 15 epochs
- Everything else the same

[10]:
```
f.manual_forecast(
    layers_struct=[('LSTM',{'units':100,'dropout':0.2})],
    epochs=15,
    validation_split=0.2,
    plot_loss=True,
    call_me="lstm_1layer",
    verbose=0, # so it doesn't print each epoch and saves space in the notebook
)
```

```
1/1 [==============================] - 0s 216ms/step
```



```
1/1 [==============================] - 0s 219ms/step
88/88 [==============================] - 3s 29ms/step
```

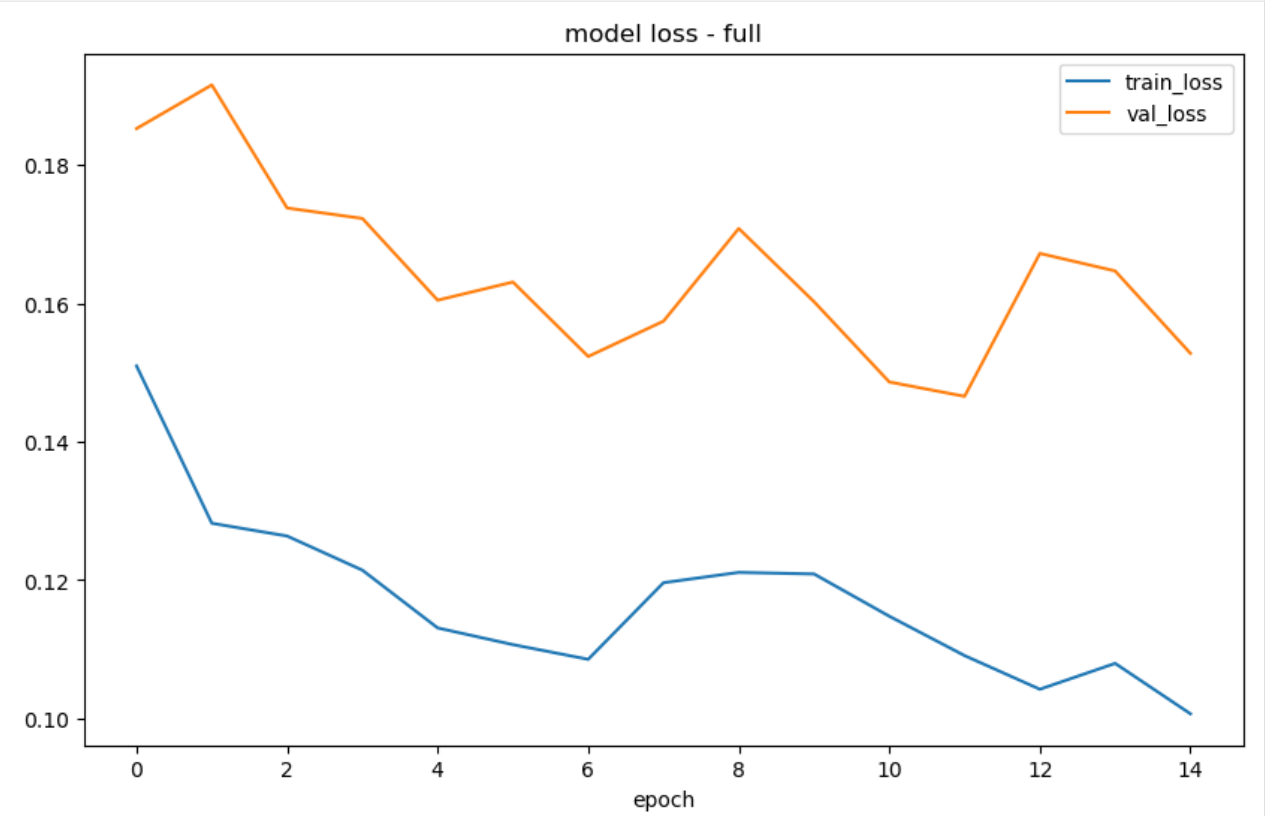


16.2.2.2 Layered Model

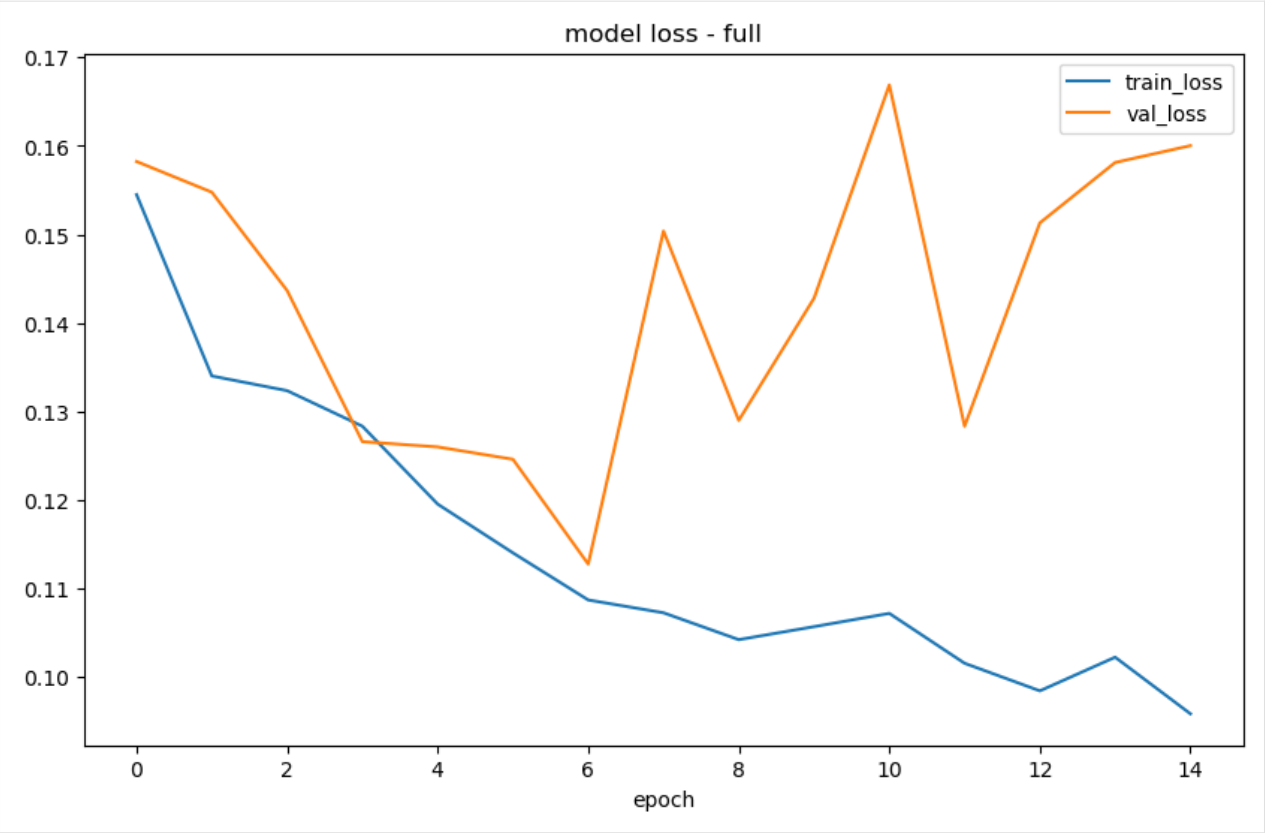
- 2 lstm layers and 2 dense layers
- No dropout

[11]:
```
f.manual_forecast(
    layers_struct=[
        ('LSTM',{'units':100,'dropout':0})
    ] * 2 + [
        ('Dense',{'units':10})
    ] * 2,
    epochs=15,
    random_seed=42,
    plot_loss=True,
    validation_split=0.2,
    call_me='lstm_layered',
    verbose=0
)
```

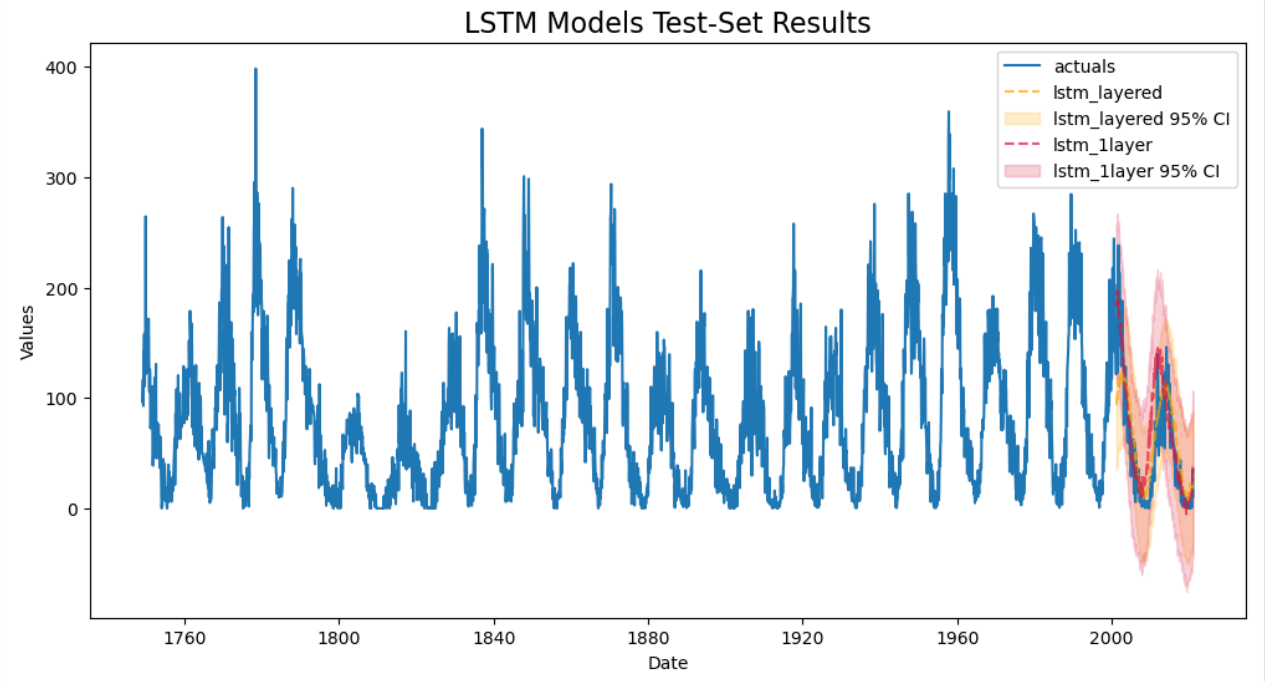
```
1/1 [==============================] - 0s 408ms/step
```



```
1/1 [==============================] - 0s 411ms/step
88/88 [==============================] - 5s 59ms/step
```



[12]:
```
f.plot_test_set(models=['lstm_1layer','lstm_layered'],ci=True,order_by='TestSetRMSE')
plt.title('LSTM Models Test-Set Results',size=16)
plt.show()
```



16.3 Prepare NNAR Model

- Let's try building a model you can read about here: https://otexts.com/fpp2/nnetar.html
- This is a time-series based dense neural network model, where the final predictions are the average of several models with randomly selected starting weights
- It is not a recurrent neural network and does not use the rnn estimator, but I thought it'd be fun to demonstrate here.
- It takes three input parameters:
- p (number of lags)
- P (number of seasonal lags)
- m (seasonal period)
- It also accepts exogenous variables. We add a time trend, monthly seasonality in wave functions, and a 120-period cycle
- Another parameter to consider is k: the size of the hidden layer. By default, this is the total number of inputs divided by 2, rounded up. We will keep the default
- The default number of models to average is 20 and we will keep that default as well
- See the model's documentation in R: https://www.rdocumentation.org/packages/forecast/versions/8.16/topics/nnetar

[13]:
```
p = 10 # non-seasonal lags
P = 6  # seasonal lags
m = 12 # seasonal period

f.drop_all_Xvars()
f.add_ar_terms(p)
f.add_AR_terms((P,m))

# in addition to the process described in the linked book, we can add monthly␣
↪seasonality in a fourier transformation
f.add_seasonal_regressors('month',raw=False,sincos=True)
# lastly, we add an irregular 10-year cycle that is idionsycratic to this dataset
f.add_cycle(120)
```

[14]:
```
f
```

[14]:
```
Forecaster(
    DateStartActuals=1749-01-31T00:00:00.000000000
    DateEndActuals=2021-01-31T00:00:00.000000000
    Freq=M
    N_actuals=3265
    ForecastLength=240
    Xvars=['AR1', 'AR2', 'AR3', 'AR4', 'AR5', 'AR6', 'AR7', 'AR8', 'AR9', 'AR10', 'AR12',
↪ 'AR24', 'AR36', 'AR48', 'AR60', 'AR72', 'monthsin', 'monthcos', 'cycle120sin',
↪'cycle120cos']
    TestLength=240
    ValidationMetric=rmse
    ForecastsEvaluated=['rnn_1layer', 'rnn_layered', 'lstm_1layer', 'lstm_layered']
    CILevel=0.95
```

(continues on next page)

(continued from previous page)

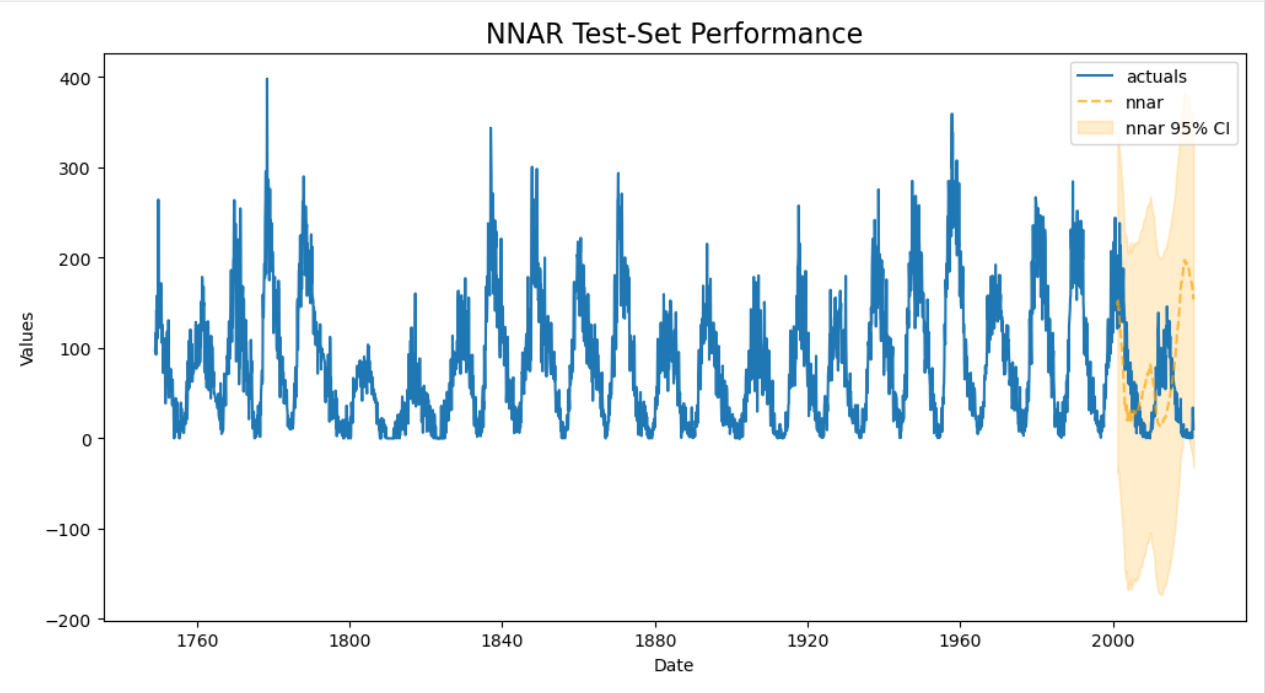
```
    CurrentEstimator=rnn
    GridsFile=Grids
)
```

16.4 Forecast NNAR Model

[15]:
```
# the default parameter used in the book is the total number of inputs divided by 2,␣
↪rounded up
k = int(np.ceil(len(f.get_regressor_names())/2))
repeats = 20 # default repeats number used in book
f.set_estimator('mlp')
for r in tqdm(range(repeats)): # repeats
    f.manual_forecast(
        hidden_layer_sizes=(k,),
        activation='relu',
        random_state=r,
        normalizer='scale',
        call_me=f'mlp_{r}',
    )
f.save_feature_importance()
# now we take the averages of all models to create the final NNAR
f.set_estimator('combo')
f.manual_forecast(how='simple',models=[f'mlp_{r}' for r in range(20)],call_me='nnar')
```

```
  0%|          | 0/20 [00:00<?, ?it/s]
```

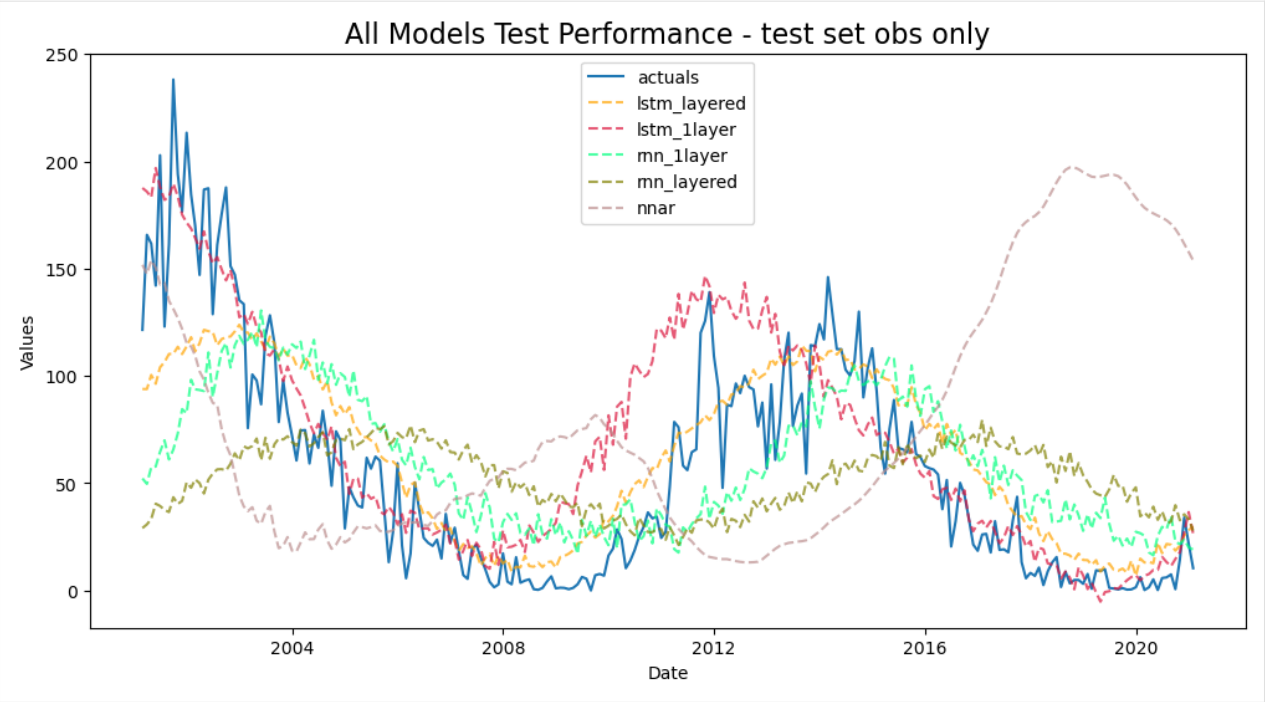
[16]:
```
f.plot_test_set(ci=True,models='nnar')
plt.title('NNAR Test-Set Performance',size=16)
plt.show()
```



This doesn't look as good as any of our evaluated RNN models.

One thing we notice with all these test-set graphs is that the precise deviations from the trend are hard to see because the series is so large. Let's call the function again with all evaluated models ordered by test RMSE and zoomed in to the test-set section of the series only by setting `include_train=False`.

[17]:
```
f.plot_test_set(
    models=['rnn_1layer','rnn_layered','lstm_1layer','lstm_layered','nnar'],
    order_by='TestSetRMSE',
    include_train=False,
)
plt.title('All Models Test Performance - test set obs only',size=16)
plt.show()
```



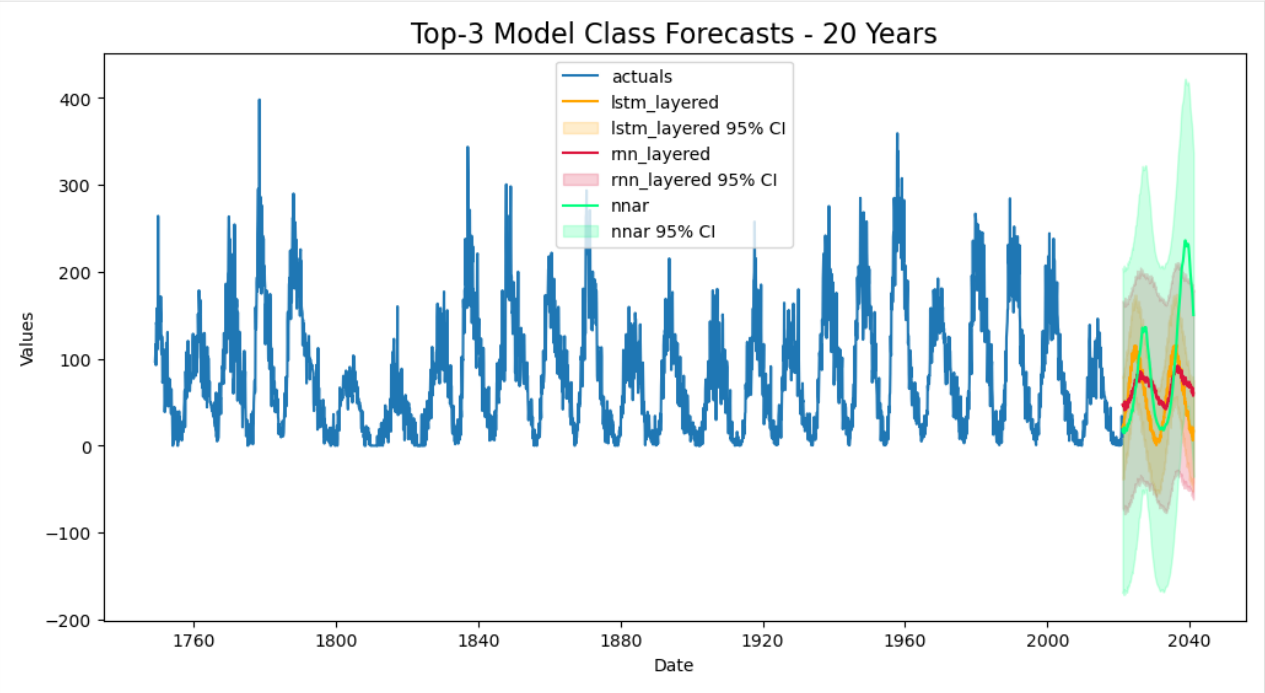
With this view, it is not clear that any model did as well as we might have thought from the other graphs.

16.5 Compare All Models

16.5.1 Forecast Plot

- best rnn model
- best lstm model
- nnar model

[18]:
```
f.plot(models=['rnn_layered','lstm_layered','nnar'],order_by='TestSetRMSE',ci=True)
plt.title('Top-3 Model Class Forecasts - 20 Years',size=16)
plt.show()
```



16.5.2 Export Model Summaries for all applied models

[19]:
```
pd.set_option('display.float_format',  '{:.4f}'.format)
f.export(
    'model_summaries',
    models=['rnn_1layer','rnn_layered','lstm_1layer','lstm_layered','nnar'],
    determine_best_by = 'TestSetRMSE',
)[
    [
        'ModelNickname',
        'TestSetRMSE',
        'TestSetR2',
        'InSampleRMSE',
        'InSampleR2',
        'best_model'
    ]
]
```

[19]:

	ModelNickname	TestSetRMSE	TestSetR2	InSampleRMSE	InSampleR2	best_model
0	lstm_layered	28.5508	0.7083	56.6811	0.3310	True
1	lstm_1layer	31.8674	0.6366	43.3984	0.6078	False
2	rnn_1layer	41.2311	0.3918	68.7316	0.0163	False
3	rnn_layered	55.6165	-0.1067	60.6494	0.2341	False
4	nnar	92.0142	-2.0293	28.4102	0.8266	False

16.5.3 Backtest Best Model

The LSTM with four layers appears to be our most accurate model out of the 5 we ran and showed. The NNAR model, in spite of being fun to set up, was the worst. With more time spent, even better results could be extracted. Although that model appears accurate on the test set we gave to it, an interesting question is how good it would have been if we had used it in production for the last 5 years. That's what backtesting allows us to evaluate. Backtesting can take a long time for more complex models.

[32]:
```
from scalecast.Pipeline import Pipeline
from scalecast.util import backtest_metrics

def forecaster(f):
    f.auto_Xvar_select(
        try_trend = False,
        irr_cycles = [120,132,144],
        cross_validate = True,
        cvkwargs = {'k':3},
        dynamic_tuning = 240,
        max_ar = 240,
    )
    f.set_estimator('rnn')
    f.manual_forecast(
        layers_struct=[
            ('LSTM',{'units':100,'dropout':0})
        ] * 2 + [
            ('Dense',{'units':10})
        ] * 2,
        epochs=15,
        random_seed=42,
        validation_split=0.2,
        call_me='lstm_layered',
        verbose=0
    )

pipeline = Pipeline(steps = [('Forecast',forecaster)])
```

[33]:
```
# default args below
backtest_results = pipeline.backtest(
    f,
    n_iter=5,
    fcst_length = 240,
    test_length = 0,
    jump_back = 12, # place a year between consecutive training sets
    cis = False,
)
bm = backtest_metrics(backtest_results,mets=['r2','rmse'])
bm
```

```
1/1 [==============================] - 0s 439ms/step
80/80 [==============================] - 5s 63ms/step
1/1 [==============================] - 0s 418ms/step
80/80 [==============================] - 5s 67ms/step
1/1 [==============================] - 0s 414ms/step
79/79 [==============================] - 5s 67ms/step
```

(continues on next page)

(continued from previous page)

```
1/1 [==============================] - 0s 435ms/step
79/79 [==============================] - 6s 70ms/step
1/1 [==============================] - 0s 390ms/step
80/80 [==============================] - 5s 58ms/step
```

[33]:

Model	Metric	Iter0	Iter1	Iter2	Iter3	Iter4	Average
lstm_layered	r2	0.7385	0.3077	0.3695	0.3589	0.2503	0.4050
	rmse	27.0322	48.1908	46.7773	45.9266	49.2748	43.4403

[34]:

```
rmse = bm.loc[('lstm_layered','rmse'),'Average']
r2 = bm.loc[('lstm_layered','r2'),'Average']

print(
    'This shows that if we had used this model on actual data in the previous 5 years,'
    f' it would have obtained an average RMSE of {rmse:.1f} and R2 of {r2:.1%}.'
)
```

```
This shows that if we had used this model on actual data in the previous 5 years, it␣
↪would have obtained an average RMSE of 43.4 and R2 of 40.5%.
```

CHAPTER

SEVENTEEN

SCIKIT-LEARN MODELS

This notebook showcases the scalecast wrapper around scikit-learn models.

The data is available for download here: https://www.kaggle.com/datasets/bobnau/daily-website-visitors
See the blog post:
https://medium.com/towards-data-science/expand-your-time-series-arsenal-with-these-models-10c807d37558

[1]:
```
import pandas as pd
import numpy as np
import pandas_datareader as pdr
import matplotlib
import matplotlib.pyplot as plt
import seaborn as sns
from dateutil.relativedelta import relativedelta
from scalecast.Forecaster import Forecaster
from scalecast import GridGenerator
from scalecast.auxmodels import mlp_stack
from tqdm.notebook import tqdm
from sklearn.ensemble import BaggingRegressor
from sklearn.ensemble import StackingRegressor
from sklearn.neural_network import MLPRegressor

pd.set_option('max_colwidth',500)
pd.set_option('display.max_rows',500)
```

[2]:
```
def plot_test_export_summaries(f):
    """ exports the relevant statisitcal information and displays a plot of the test-set␣
↪results for the last model run
    """
    f.plot_test_set(models=f.estimator,ci=True)
    plt.title(f'{f.estimator} test-set results',size=16)
    plt.show()
    return f.export('model_summaries',determine_best_by='TestSetMAPE')[
        [
            'ModelNickname',
            'HyperParams',
            'TestSetMAPE',
            'TestSetR2',
```

(continues on next page)

(continued from previous page)

```
            'InSampleMAPE',
            'InSampleR2'
        ]
    ]
```

We will bring in the default grids from scalecast and tune some of our models this way. For others, we will create our own grids.

[3]:
```
GridGenerator.get_example_grids()
```

[4]:
```
data = pd.read_csv('daily-website-visitors.csv')
data.head()
```

[4]:
```
   Row        Day  Day.Of.Week       Date Page.Loads Unique.Visits  \
0    1     Sunday            1  9/14/2014      2,146         1,582
1    2     Monday            2  9/15/2014      3,621         2,528
2    3    Tuesday            3  9/16/2014      3,698         2,630
3    4  Wednesday            4  9/17/2014      3,667         2,614
4    5   Thursday            5  9/18/2014      3,316         2,366

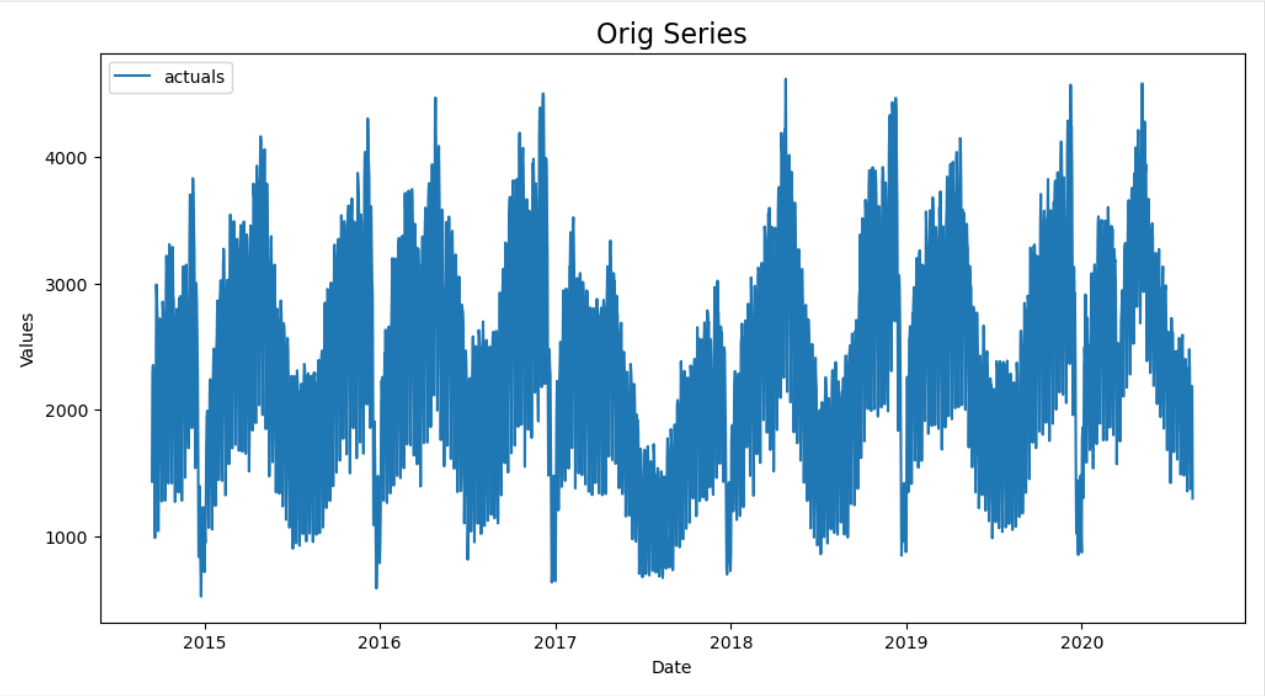
2               2352              278
3               2327              287
4               2130              236
```

[5]:
```
data.shape
```

[5]:
```
(2167, 8)
```

[6]:
```
f=Forecaster(y=data['First.Time.Visits'],current_dates=data['Date'])
f.plot()
plt.title('Orig Series',size=16)
plt.show()
```



Not all models we will showcase come standard in scalecast, but we can easily add them by using the code below:

[7]:
```
f.add_sklearn_estimator(BaggingRegressor,'bagging')
f.add_sklearn_estimator(StackingRegressor,'stacking')
```

For more EDA on this dataset, see the prophet example: https://scalecast-examples.readthedocs.io/en/latest/prophet/prophet.html#EDA

17.1 Prepare Forecast

- 60-day forecast horizon
- 20% test split
- Turn confidence intervals on
- Add time series regressors:
- 7 autoregressive terms
- 4 seasonal autoregressive terms spaced 7-periods apart
- month, quarter, week, and day of year with a fournier transformation
- dayofweek, leap year, and week as dummy variables
- year

[8]:
```
fcst_length = 60
f.generate_future_dates(fcst_length)
f.set_test_length(.2)
f.eval_cis() # tell the object to build confidence intervals for all models
f.add_ar_terms(7)
```

(continues on next page)

(continued from previous page)

```
f.add_AR_terms((4,7))
f.add_seasonal_regressors('month','quarter','week','dayofyear',raw=False,sincos=True)
f.add_seasonal_regressors('dayofweek','is_leap_year','week',raw=False,dummy=True,drop_
↪first=True)
f.add_seasonal_regressors('year')
f
```

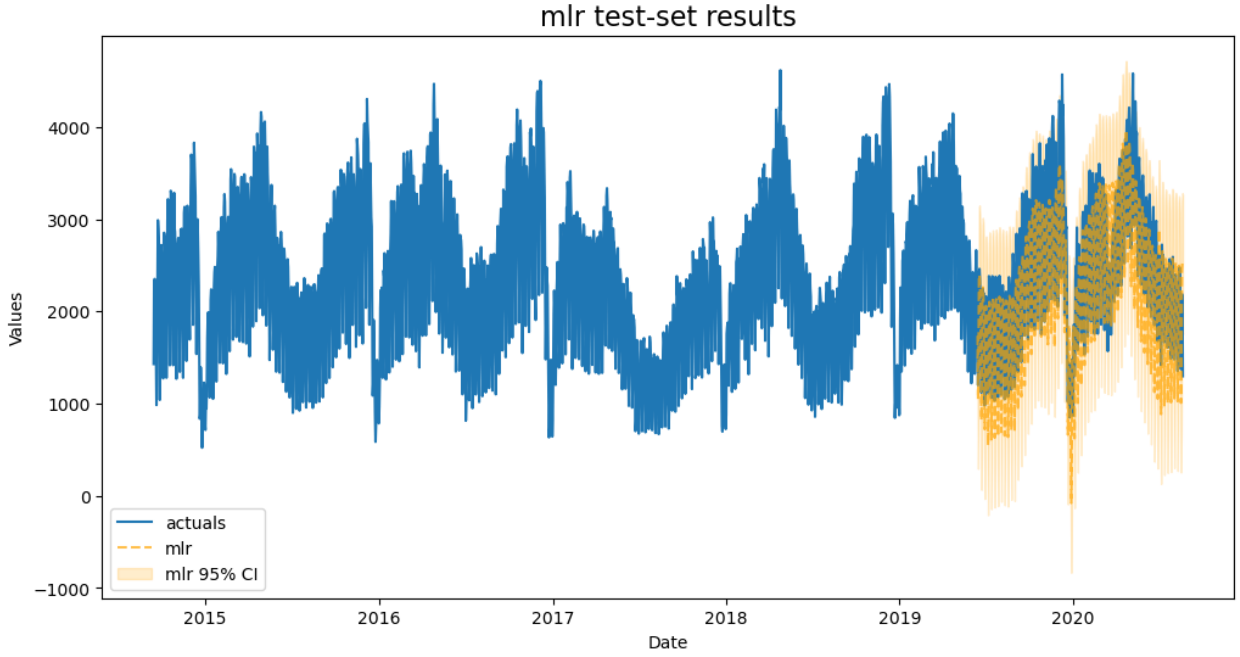
[8]:
```
Forecaster(
    DateStartActuals=2014-09-14T00:00:00.000000000
    DateEndActuals=2020-08-19T00:00:00.000000000
    Freq=D
    N_actuals=2167
    ForecastLength=60
    Xvars=['AR1', 'AR2', 'AR3', 'AR4', 'AR5', 'AR6', 'AR7', 'AR14', 'AR21', 'AR28',
↪'monthsin', 'monthcos', 'quartersin', 'quartercos', 'weeksin', 'weekcos', 'dayofyearsin
↪', 'dayofyearcos', 'dayofweek_1', 'dayofweek_2', 'dayofweek_3', 'dayofweek_4',
↪'dayofweek_5', 'dayofweek_6', 'is_leap_year_True', 'week_10', 'week_11', 'week_12',
↪'week_13', 'week_14', 'week_15', 'week_16', 'week_17', 'week_18', 'week_19', 'week_2',
↪'week_20', 'week_21', 'week_22', 'week_23', 'week_24', 'week_25', 'week_26', 'week_27',
↪ 'week_28', 'week_29', 'week_3', 'week_30', 'week_31', 'week_32', 'week_33', 'week_34',
↪ 'week_35', 'week_36', 'week_37', 'week_38', 'week_39', 'week_4', 'week_40', 'week_41',
↪ 'week_42', 'week_43', 'week_44', 'week_45', 'week_46', 'week_47', 'week_48', 'week_49
↪', 'week_5', 'week_50', 'week_51', 'week_52', 'week_53', 'week_6', 'week_7', 'week_8',
↪'week_9', 'year']
    TestLength=433
    ValidationMetric=rmse
    ForecastsEvaluated=[]
    CILevel=0.95
    CurrentEstimator=mlr
    GridsFile=Grids
)
```

17.2 MLR

- use default parameters (which means all input vars are scaled with a minmax scaler by default for all sklearn models)

[9]:
```
f.set_estimator('mlr')
f.manual_forecast()
```

[10]:
```
plot_test_export_summaries(f)
```



[10]:

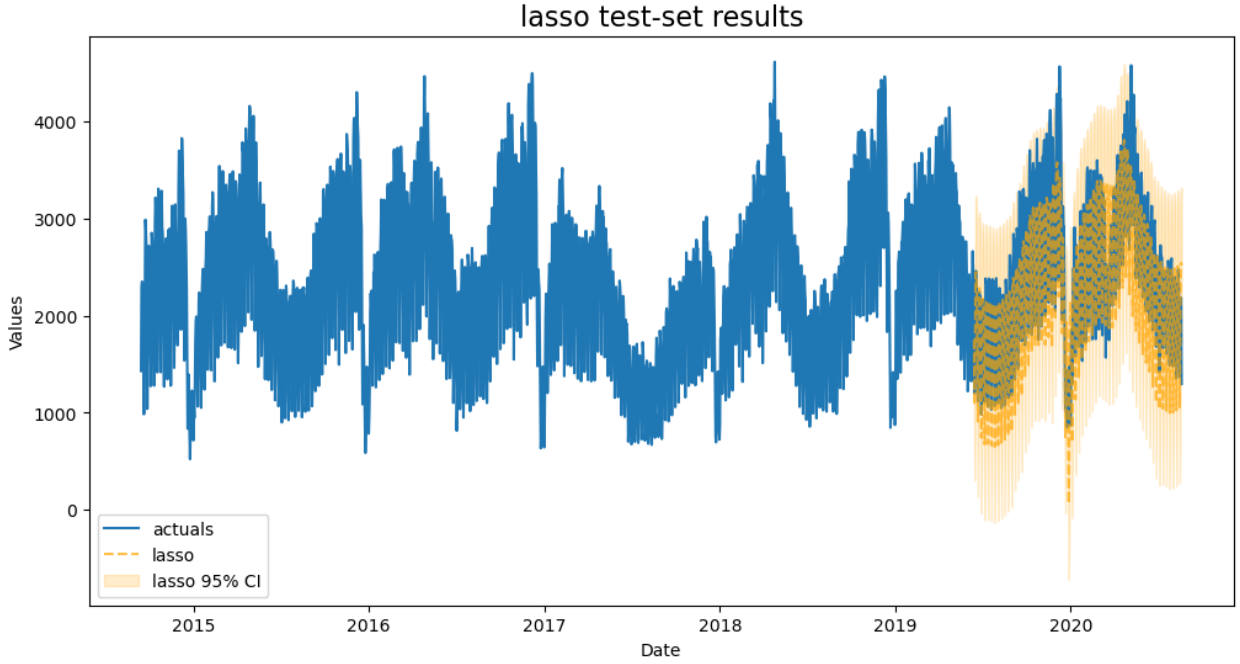
	ModelNickname	HyperParams	TestSetMAPE	TestSetR2	InSampleMAPE	InSampleR2
0	mlr	{}	0.14485	0.733553	0.064183	0.953482

17.3 Lasso

- tune alpha with 100 choices using 3-fold cross validation

[11]:
```
f.set_estimator('lasso')
lasso_grid = {'alpha':np.linspace(0,2,100)}
f.ingest_grid(lasso_grid)
f.cross_validate(k=3)
f.auto_forecast()
```

[12]:
```
plot_test_export_summaries(f)
```



[12]:
```
  ModelNickname                       HyperParams  TestSetMAPE  TestSetR2  \
0         lasso  {'alpha': 0.32323232323232326}     0.139526   0.744279
1           mlr                                {}     0.144850   0.733553

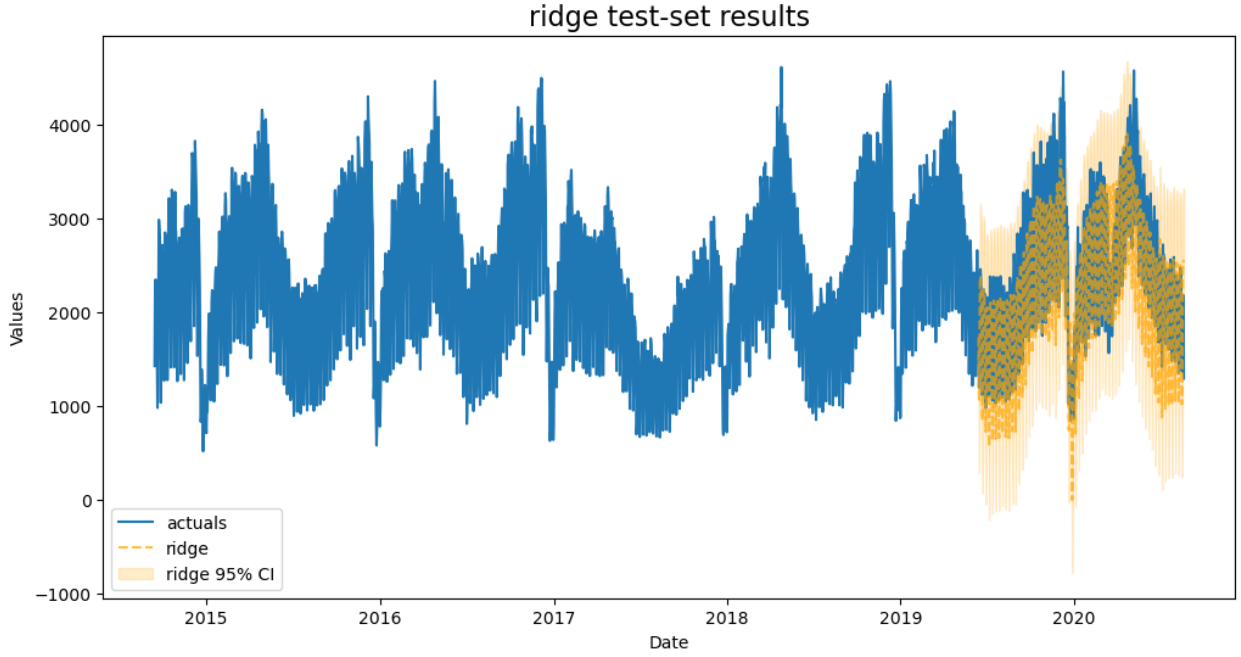
   InSampleMAPE  InSampleR2
0      0.065458    0.952205
1      0.064183    0.953482
```

17.4 Ridge

- tune alpha with the same grid used for lasso

[13]:
```
f.set_estimator('ridge')
f.ingest_grid(lasso_grid)
f.cross_validate(k=3)
f.auto_forecast()
```

[14]:
```
plot_test_export_summaries(f)
```



[14]:
```
  ModelNickname                    HyperParams  TestSetMAPE  TestSetR2  \
0         lasso  {'alpha': 0.32323232323232326}     0.139526   0.744279
1         ridge   {'alpha': 0.6060606060606061}     0.140560   0.743738
2           mlr                             {}     0.144850   0.733553

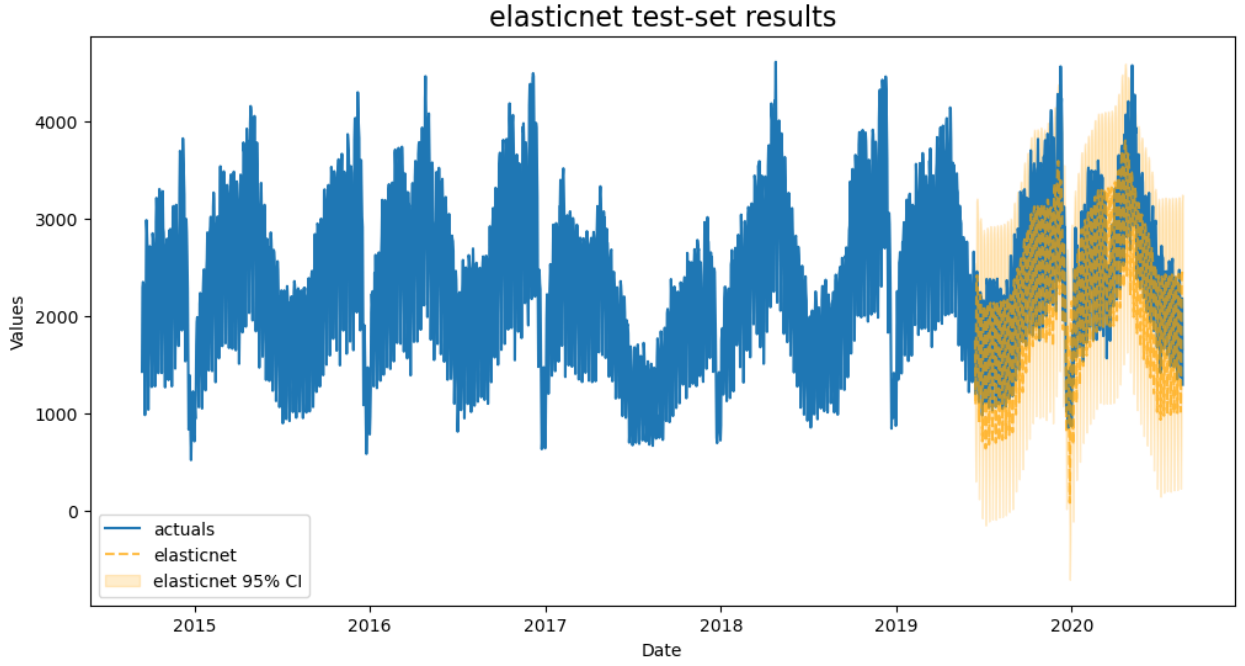
   InSampleMAPE  InSampleR2
0      0.065458    0.952205
1      0.064592    0.952812
2      0.064183    0.953482
```

17.5 Elasticnet

- this model mixes L1 and L2 regularization parameters
- its default grid is pretty good for finding the optimal alpha value and l1 ratio

[15]:
```
f.set_estimator('elasticnet')
f.cross_validate(k=3)
f.auto_forecast()
```

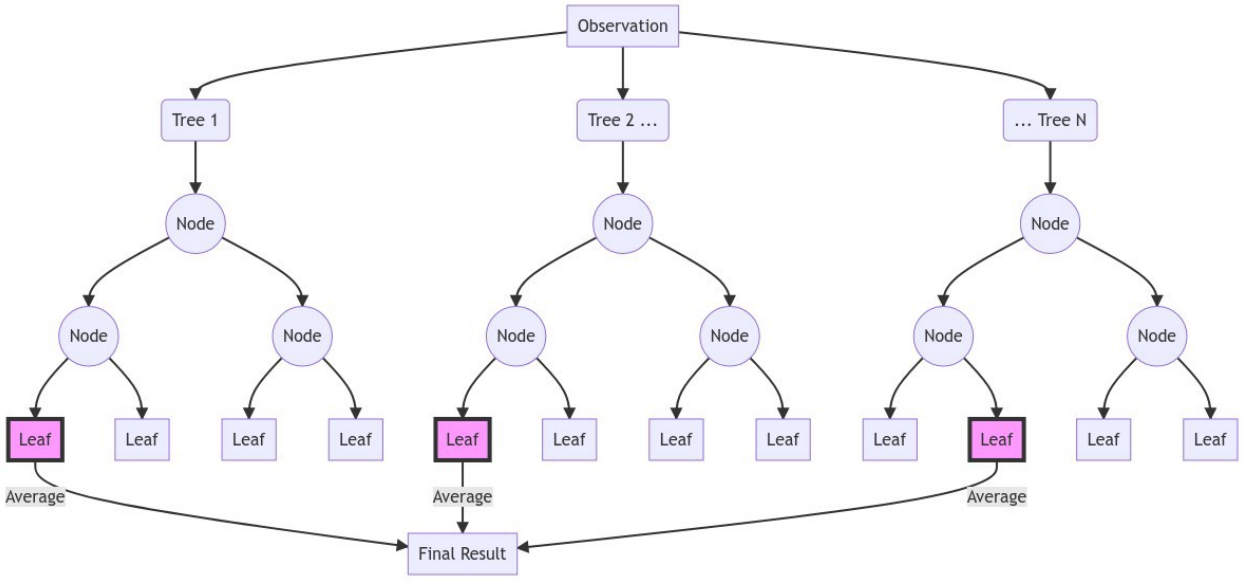
[16]:
```
plot_test_export_summaries(f)
```



[16]:

	ModelNickname	HyperParams	TestSetMAPE	TestSetR2	InSampleMAPE	InSampleR2
0	lasso	{'alpha': 0.32323232323232326}	0.139526	0.744279	0.065458	0.952205
1	ridge	{'alpha': 0.6060606060606061}	0.140560	0.743738	0.064592	0.952812
2	elasticnet	{'alpha': 2.0, 'l1_ratio': 1, 'normalizer': 'scale'}	0.141774	0.733125	0.065364	0.952024
3	mlr	{}	0.144850	0.733553	0.064183	0.953482

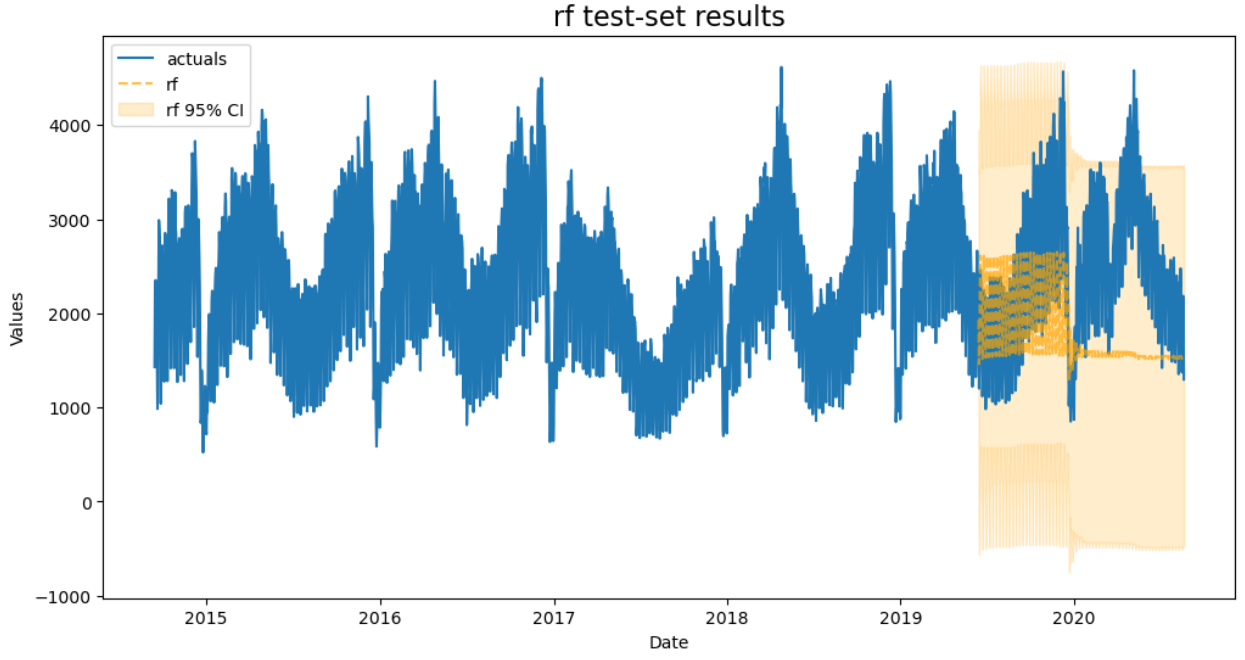
17.6 RF



create a grid to tune Random Forest with more options than what is available in the default grids

[17]:
```
f.set_estimator('rf')
rf_grid = {
    'max_depth':[2,3,4,5],
    'n_estimators':[100,200,500],
    'max_features':['auto','sqrt','log2'],
    'max_samples':[.75,.9,1],
}
f.ingest_grid(rf_grid)
f.cross_validate(k=3)
f.auto_forecast()
```

[18]:
```
plot_test_export_summaries(f)
```



[18]:

	ModelNickname	HyperParams	TestSetMAPE	TestSetR2	InSampleMAPE	InSampleR2
0	lasso	{'alpha': 0.32323232323232326}	0.139526	0.744279	0.065458	0.952205
1	ridge	{'alpha': 0.6060606060606061}	0.140560	0.743738	0.064592	0.952812
2	mlr	{}	0.144850	0.733553	0.064183	0.953482
3	elasticnet	{'alpha': 2.0, 'l1_ratio': 0, 'normalizer': None}	0.259322	0.152033	0.092402	0.904719
4	rf	{'max_depth': 5, 'n_estimators': 200, 'max_features': 'auto', 'max_samples': 0.75}	0.318096	-0.916329	0.083374	0.918095

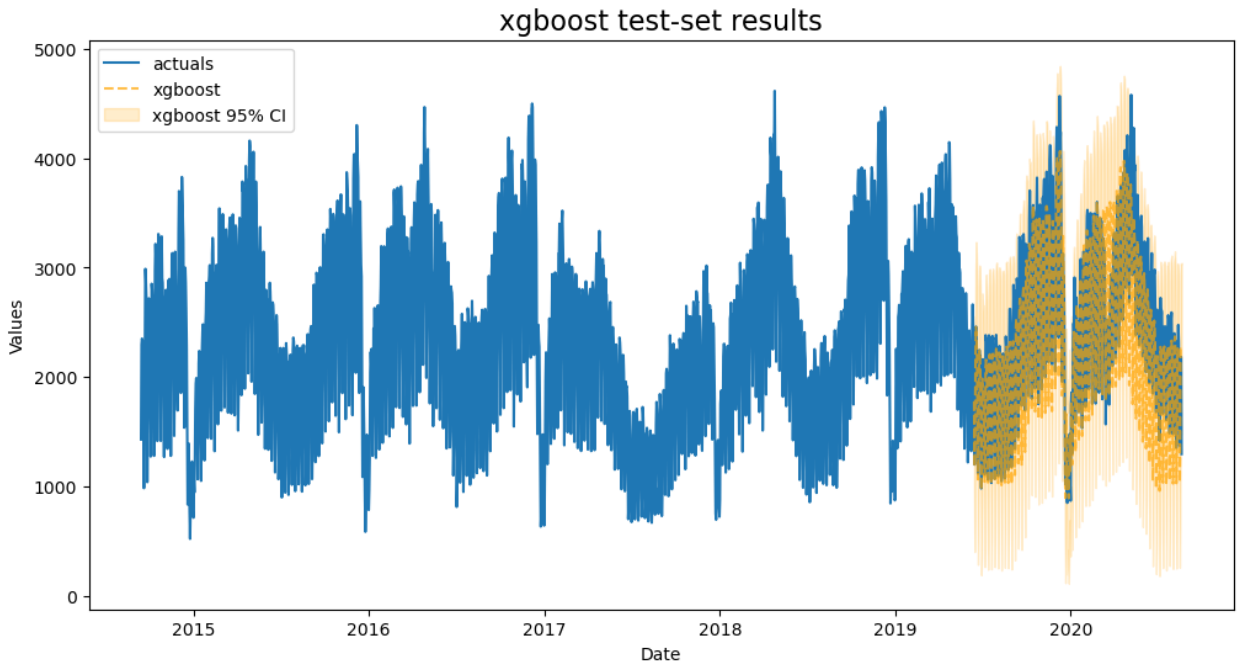
So far, both using a visual inspection and examing its test-set performance, Random Forest does worse than all others.

17.7 XGBoost

- Build a grid to tune XGBoost

[19]:
```
f.set_estimator('xgboost')
xgboost_grid = {
     'n_estimators':[150,200,250],
     'scale_pos_weight':[5,10],
     'learning_rate':[0.1,0.2],
     'gamma':[0,3,5],
     'subsample':[0.8,0.9]
}
f.ingest_grid(xgboost_grid)
f.cross_validate(k=3)
f.auto_forecast()
```

[20]:
```
plot_test_export_summaries(f)
```



[20]:
```
  ModelNickname  \
0       xgboost
1         lasso
2         ridge
3           mlr
4    elasticnet
5            rf

↪HyperParams  \
0  {'n_estimators': 150, 'scale_pos_weight': 5, 'learning_rate': 0.1, 'gamma': 5,
↪'subsample': 0.9}
1                                                                {'alpha': 0.
```

(continues on next page)

(continued from previous page)

```
↪32323232323232326}
2                                                                    {'alpha': 0.
↪6060606060606061}
3                                                                                ␣
↪        {}
4                                                {'alpha': 2.0, 'l1_ratio': 0,
↪'normalizer': None}
5                {'max_depth': 5, 'n_estimators': 200, 'max_features': 'auto', 'max_
↪samples': 0.75}

   TestSetMAPE  TestSetR2  InSampleMAPE  InSampleR2
0     0.115551   0.769377      0.018676    0.995667
1     0.139526   0.744279      0.065458    0.952205
2     0.140560   0.743738      0.064592    0.952812
3     0.144850   0.733553      0.064183    0.953482
4     0.259322   0.152033      0.092402    0.904719
5     0.318096  -0.916329      0.083374    0.918095
```

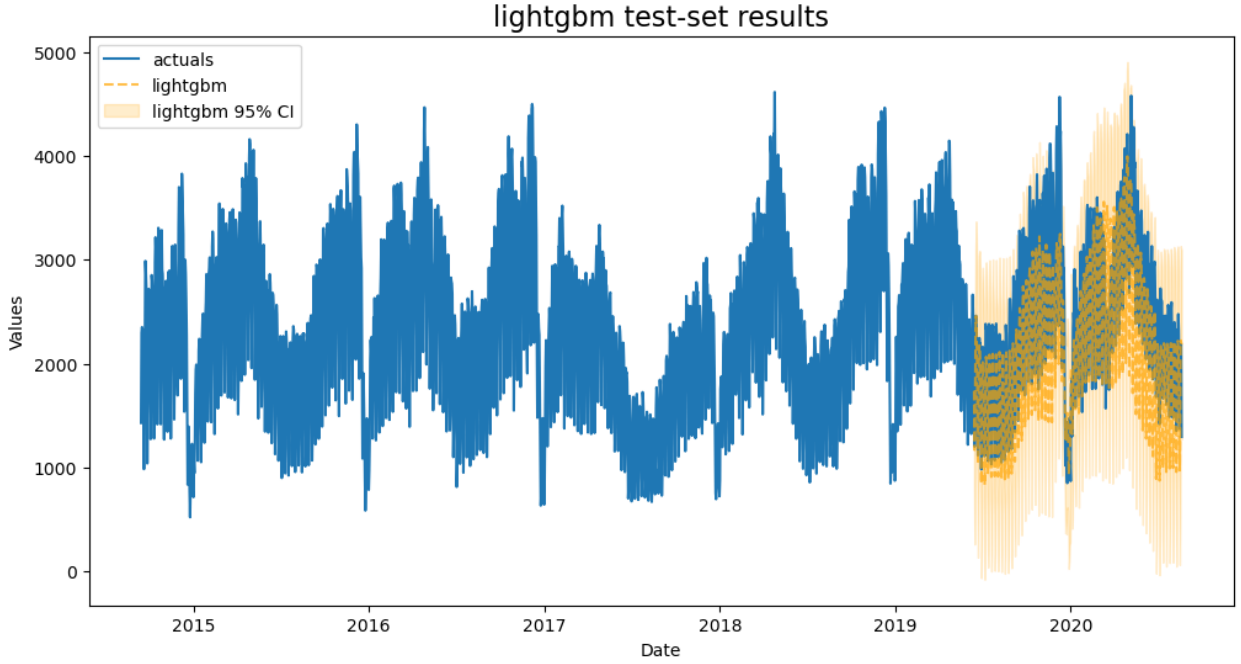
This is our best model so far using the test MAPE as the metric to determine that by. It appears to be also be highly overfit.

17.8 LightGBM

- Build a grid to tune LightGBM

[21]:
```
f.set_estimator('lightgbm')
lightgbm_grid = {
    'n_estimators':[150,200,250],
    'boosting_type':['gbdt','dart','goss'],
    'max_depth':[1,2,3],
    'learning_rate':[0.001,0.01,0.1],
    'reg_alpha':np.linspace(0,1,5),
    'reg_lambda':np.linspace(0,1,5),
    'num_leaves':np.arange(5,50,5),
}
f.ingest_grid(lightgbm_grid)
f.limit_grid_size(100,random_seed=2)
f.cross_validate(k=3)
f.auto_forecast()
```

[22]:
```
plot_test_export_summaries(f)
```



[22]:
```
  ModelNickname  \
0       xgboost
1         lasso
2         ridge
3           mlr

```

KNN is our most overfit model so far, but it fits the test-set pretty well.

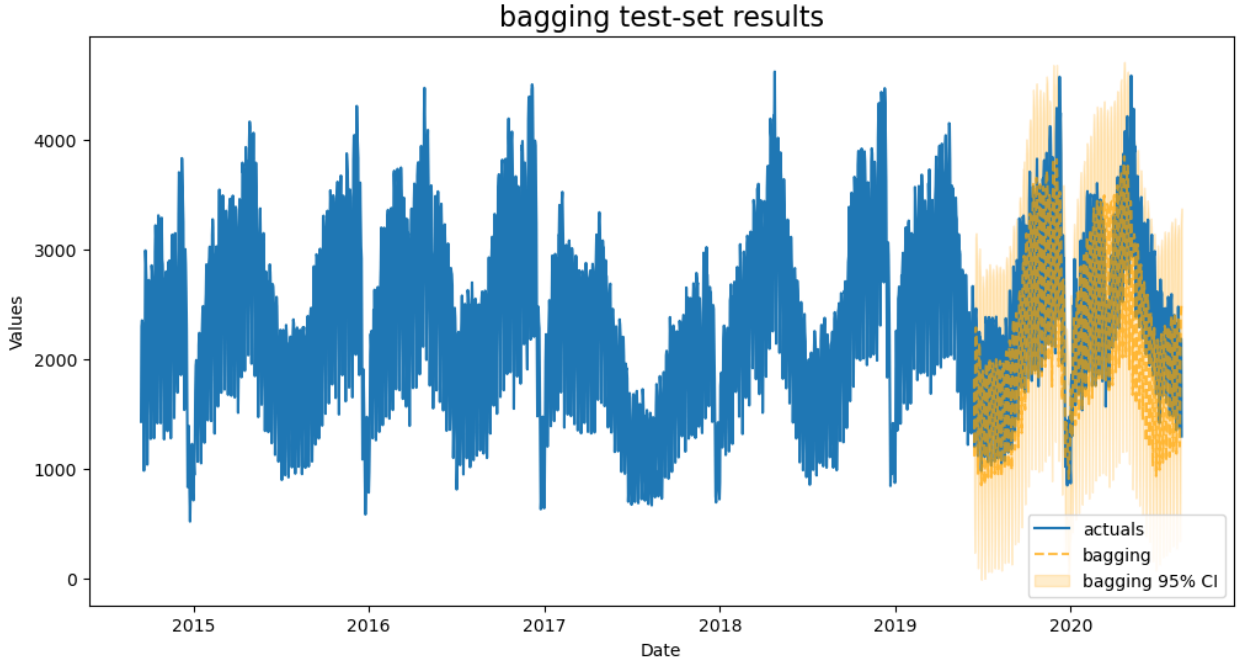
17.11 BaggingRegressor

- Like Random Forest is a bagging ensemble model using decision trees, we can use a bagging estimator that uses a three-layered mulit-level perceptron to see if the added complexity improves where the Random Forest couldn't

[28]:
```
f.set_estimator('bagging')
f.manual_forecast(
    base_estimator = MLPRegressor(
        hidden_layer_sizes=(100,100,100)
        ,solver='lbfgs'
    ),
    max_samples = 0.9,
    max_features = 0.5,
)
```

```
Finished loading model, total used 200 iterations
```

[29]:
```
plot_test_export_summaries(f)
```



[29]:
```

```

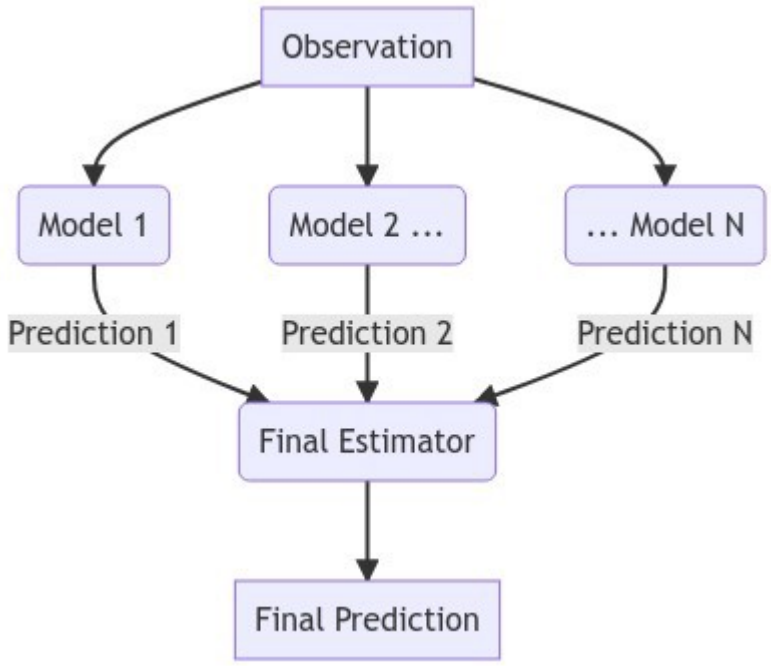
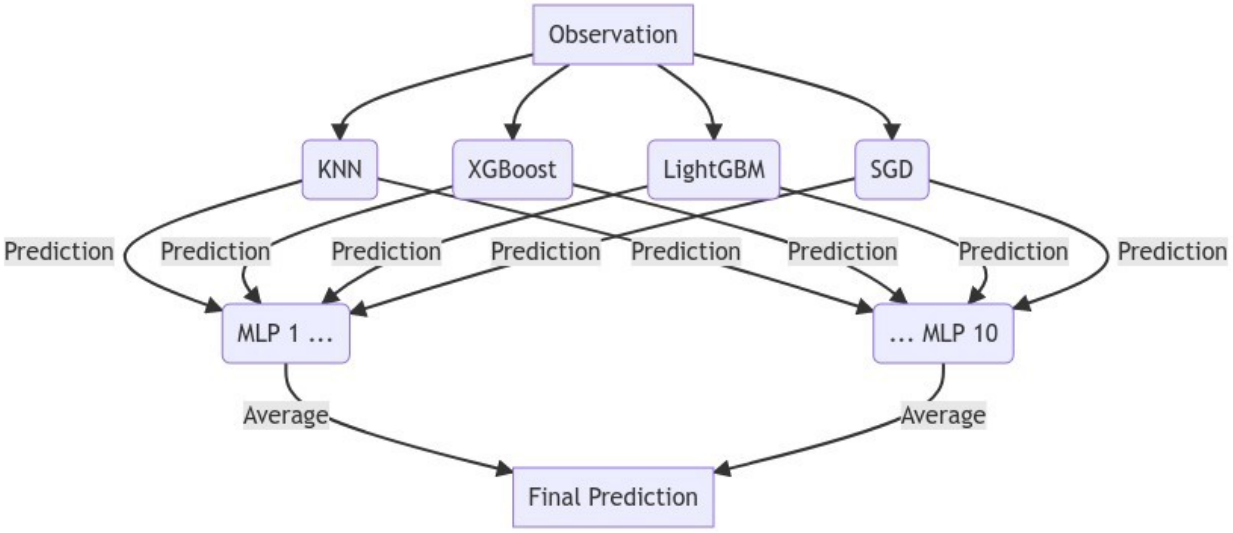
This is the best-performing model yet, with less overfitting than XGBoost and KNN.

17.12 StackingRegressor

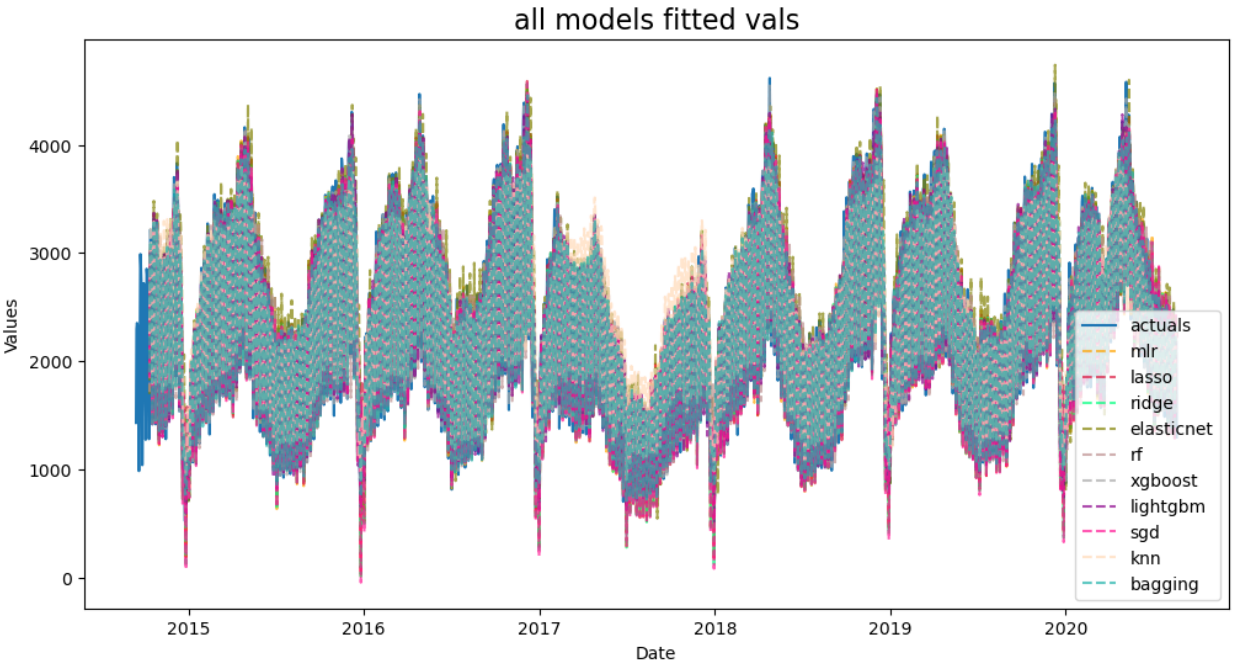
This model will use the predictions of other models as inputs to a "final estimator". It's added complexity can mean better performance, although not always.



The model that we employ uses the bagged MLP regressor from the previous section as its final estimator, and the tuned knn, xgboost, lightgbm, and sgd models as its inputs.



[30]:
```
f.plot_fitted()
plt.title('all models fitted vals',size=16)
plt.show()
```



Sometimes seeing the fitted values can give a good idea of which models to stack, as you want models that can predict both the highs and lows of the series. However, this graph didn't tell us much.

We use four of our best performing models to create the model inputs. We use a bagging estimator as the final model.

[31]:
```
f.set_estimator('stacking')
results = f.export('model_summaries')
estimators = [
    'knn',
    'xgboost',
```

CHAPTER

EIGHTEEN

STACKING MODELS

- Scalecast allows you to stack models of different classes together.
- You can add the predictions of any given model to the `Forecaster` object as a covariate, which scalecast refers to as "signals". This is through the use of the `Forecaster.add_signals()` method. See the documentation.
- These signals can come from any model class available in scalecast and are treated the same as any other covariate. They can be combined with other covariates (such as series lags, seasonal representations, and trends). They can also be added to an `MVForecaster` object for multivariate forecasting. The signals from Meta Prophet or LinkedIn Silverkite, which add holiday effects to models, can be added to the objects to capture the uniqueness of these models' specifications.
- We will use symmetric mean percentage error (SMAPE) to measure the performance of each model in this notebook.
- Requirements:
- `scalecast>=0.17.9`
- `tensorflow`
- `shap`
- Data source: M4

    )
    f = Forecaster(
        y = y,
        current_dates = cd,
        future_dates = fcst_horizon,
        test_length = fcst_horizon,
        cis = cis,
        metrics = metrics,
    )

    return f, test.values
```

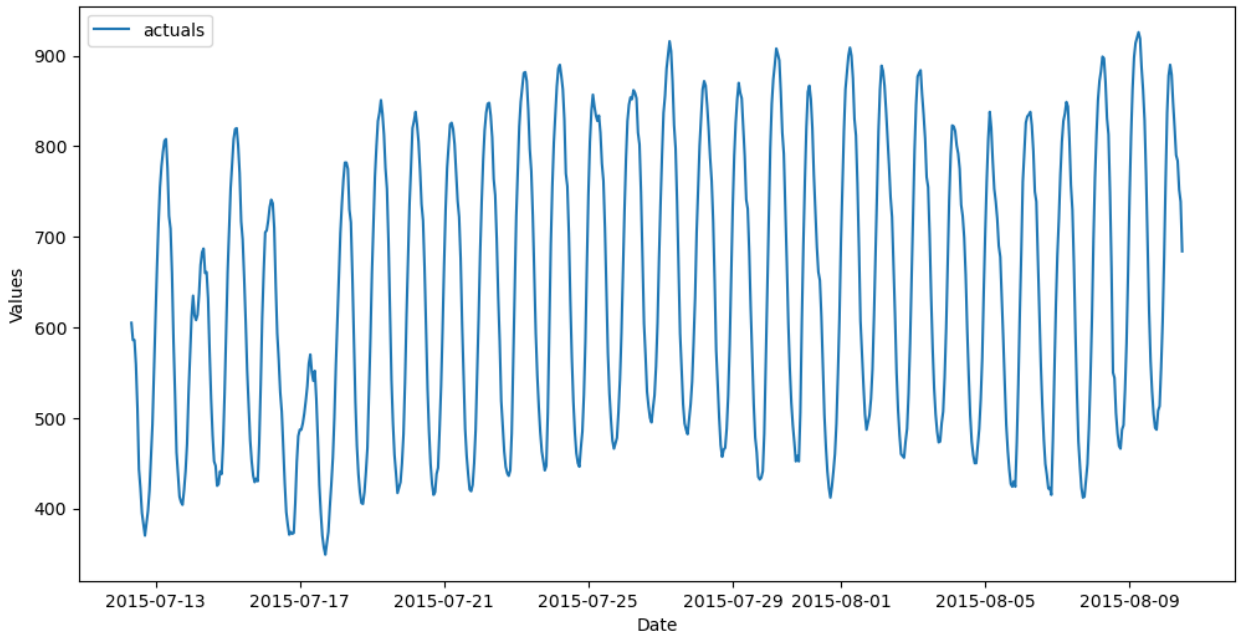
[3]:
```
f, test_set = read_data()
f
```

[3]:
```
Forecaster(
    DateStartActuals=2015-07-12T08:00:00.000000000
    DateEndActuals=2015-08-10T11:00:00.000000000
    Freq=H
    N_actuals=700
    ForecastLength=48
    Xvars=[]
    TestLength=48
    ValidationMetric=smape
    ForecastsEvaluated=[]
    CILevel=0.95
    CurrentEstimator=mlr
    GridsFile=Grids
)
```

We are using the H1 series from the M4 competition, but you can change the value passed to the `idx` argument in the function above to test this same analysis with any hourly series in the dataset.

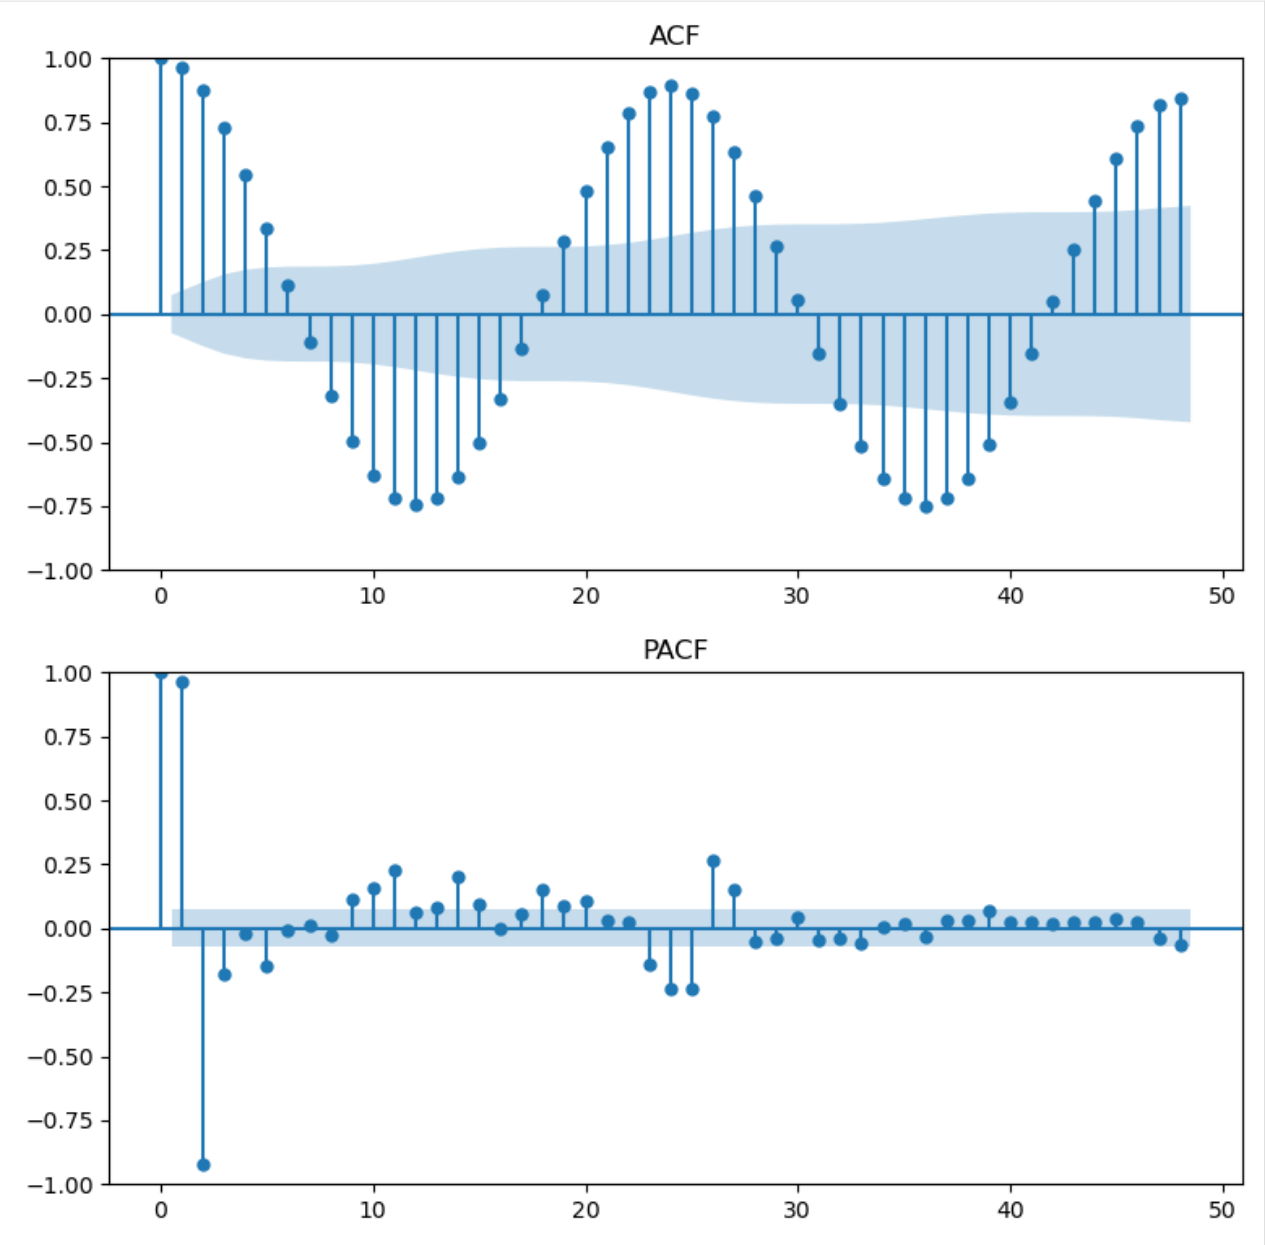
18.1 EDA

[4]:
```
f.plot()
plt.show()
```



18.1.1 ACF/PACF at Series Level

[5]:
```
figs, axs = plt.subplots(2, 1,figsize=(9,9))
f.plot_acf(ax=axs[0],title='ACF',lags=48)
f.plot_pacf(ax=axs[1],title='PACF',lags=48,method='ywm')
plt.show()
```



18.1.2 Augmented Dickey-Fuller Test

[6]:
```
critical_pval = 0.05
print('Augmented Dickey-Fuller results:')
stat, pval, _, _, _, _ = f.adf_test(full_res=True)
print('the test-stat value is: {:.2f}'.format(stat))
print('the p-value is {:.4f}'.format(pval))
print('the series is {}'.format('stationary' if pval < critical_pval else 'not stationary
↪'))
print('-'*100)
```

```
Augmented Dickey-Fuller results:
```

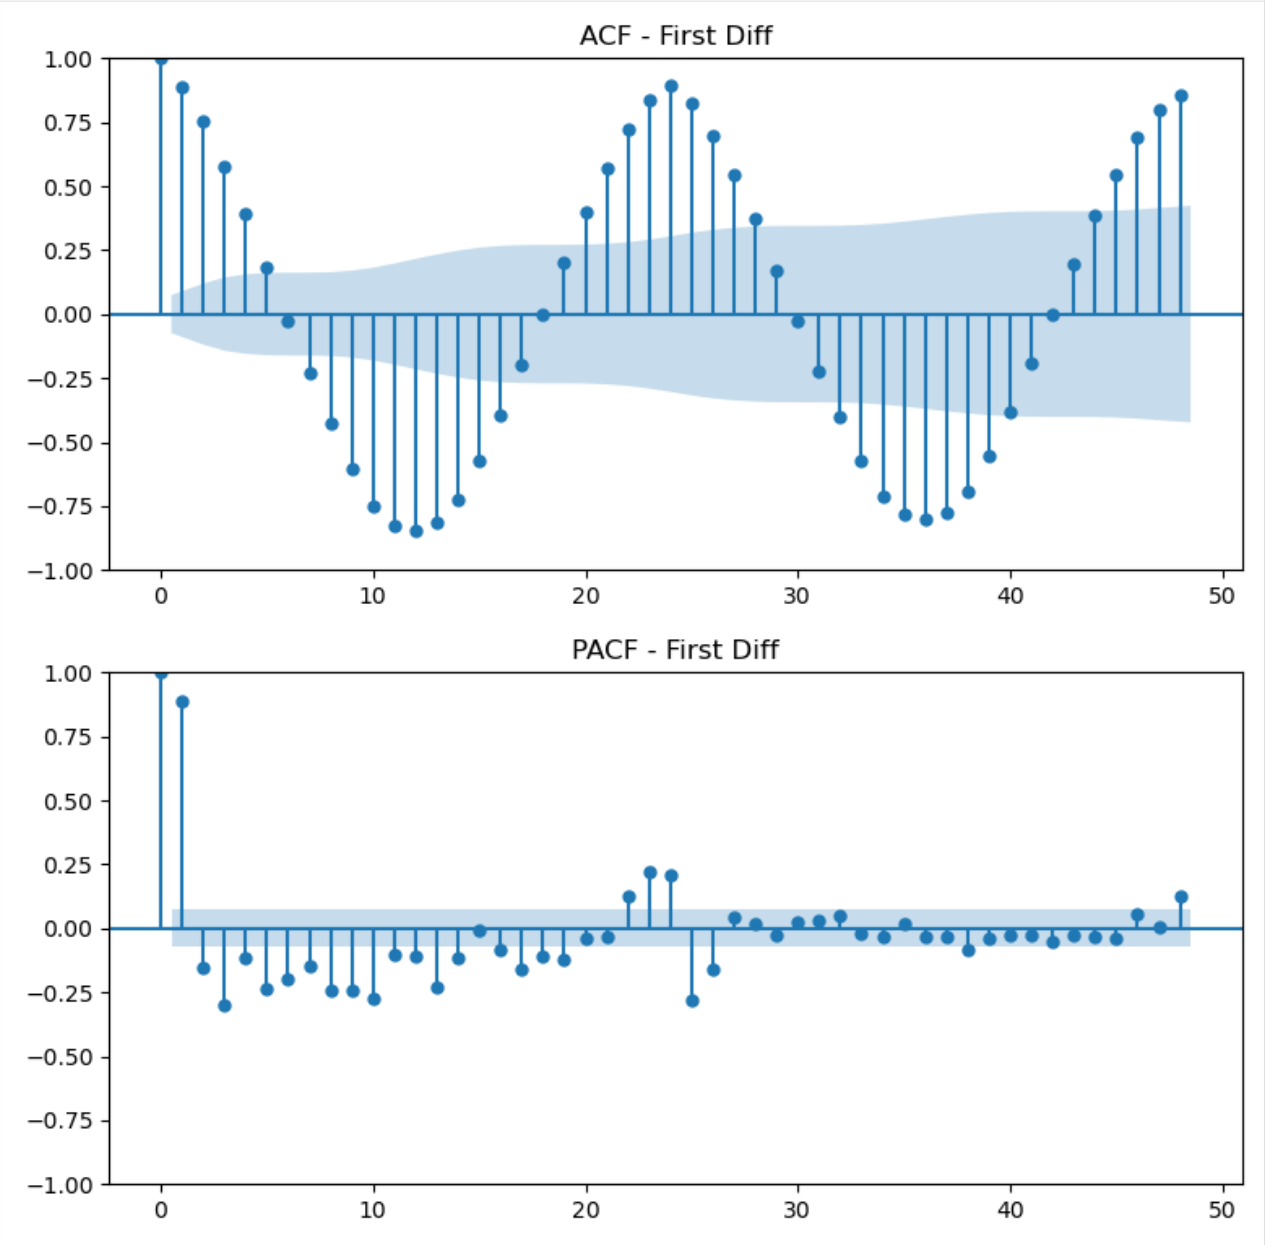
(continues on next page)

(continued from previous page)

```
the test-stat value is: -2.06
the p-value is 0.2623
the series is not stationary
-----------------------------------------------------------------------------------------
↪-----------
```

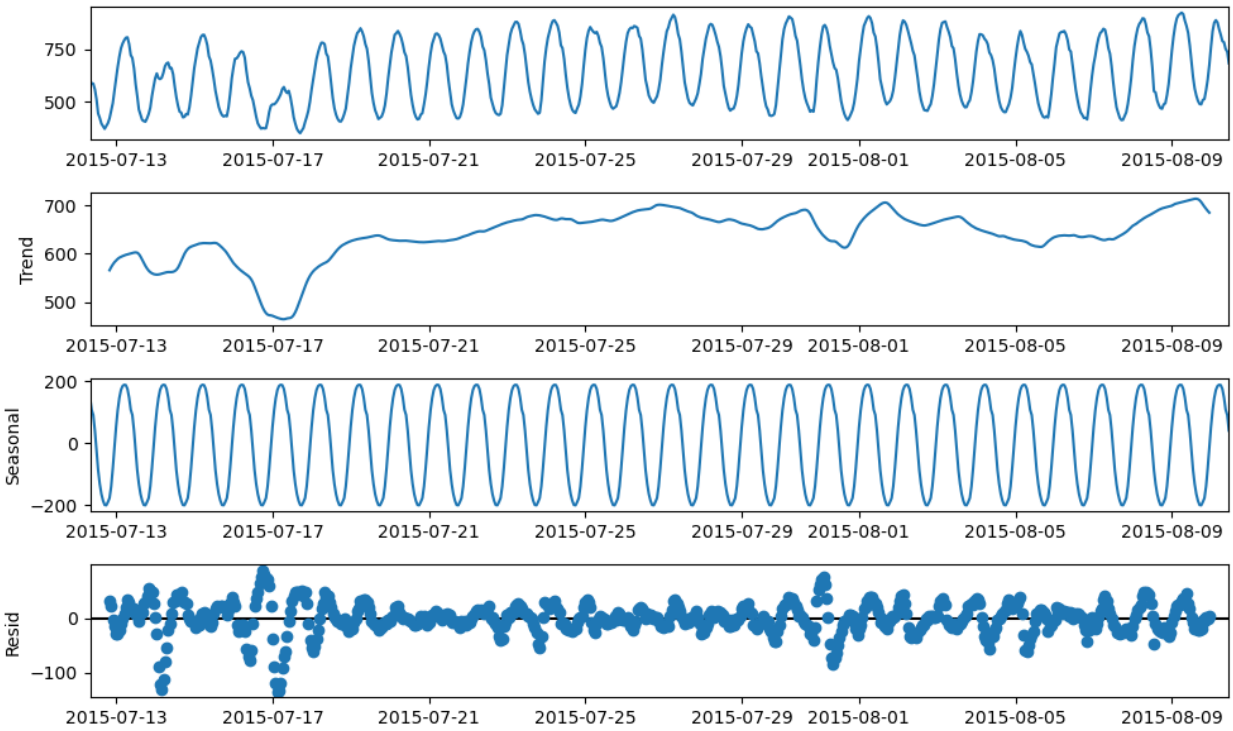
18.1.3 ACF/PACF at Series First Difference

[7]:
```
figs, axs = plt.subplots(2, 1,figsize=(9,9))
f.plot_acf(ax=axs[0],title='ACF - First Diff',lags=48,diffy=1)
f.plot_pacf(ax=axs[1],title='PACF - First Diff',lags=48,diffy=1,method='ywm')
plt.show()
```



18.1.4 Seasonal Decomp

[8]:
```
plt.rc("figure",figsize=(10,6))
f.seasonal_decompose().plot()
plt.show()
```



18.2 Naive

- This will serve as a benchmark model
- It will propagate the last 24 observations in a "seasonal naive" model

[9]:
```
f.set_estimator('naive')
f.manual_forecast(seasonal=True)
```

18.3 ARIMA

18.3.1 Manual ARIMA: (5,1,4) x (1,1,1,24)

[10]:
```
f.set_estimator('arima')
f.manual_forecast(
    order = (5,1,4),
    seasonal_order = (1,1,1,24),
    call_me = 'manual_arima',
)
```

18.4 RNN

18.4.1 Tanh Activation

[11]:
```
f.set_estimator('rnn')
f.manual_forecast(
    lags = 48,
    layers_struct=[
        ('LSTM',{'units':100,'activation':'tanh'}),
        ('LSTM',{'units':100,'activation':'tanh'}),
        ('LSTM',{'units':100,'activation':'tanh'}),
    ],
    optimizer = 'Adam',
    epochs = 15,
    plot_loss = True,
    validation_split=0.2,
    call_me = 'rnn_tanh_activation',
)
```

```

18.5 Prophet

[13]:
```
f.set_estimator('prophet')
f.manual_forecast()
```

```
11:13:36 - cmdstanpy - INFO - Chain [1] start processing
11:13:36 - cmdstanpy - INFO - Chain [1] done processing
11:13:36 - cmdstanpy - INFO - Chain [1] start processing
11:13:36 - cmdstanpy - INFO - Chain [1] done processing
```

18.6 Compare Results

[14]:
```
results = f.export(determine_best_by='TestSetSMAPE')
ms = results['model_summaries']
ms[
    [
        'ModelNickname',
        'TestSetLength',
        'TestSetSMAPE',
        'InSampleSMAPE',
    ]
]
```

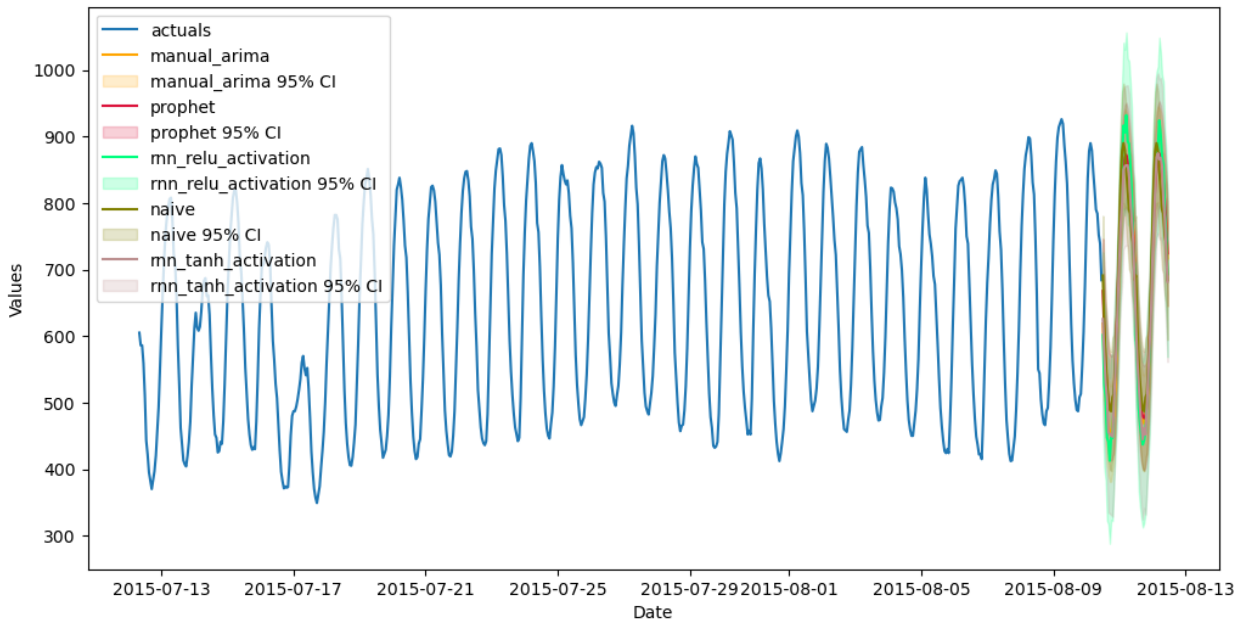
[14]:

	ModelNickname	TestSetLength	TestSetSMAPE	InSampleSMAPE
0	manual_arima	48	0.046551	0.017995
1	prophet	48	0.047237	0.043859
2	rnn_relu_activation	48	0.082511	0.081514
3	naive	48	0.093079	0.067697
4	rnn_tanh_activation	48	0.096998	0.059914

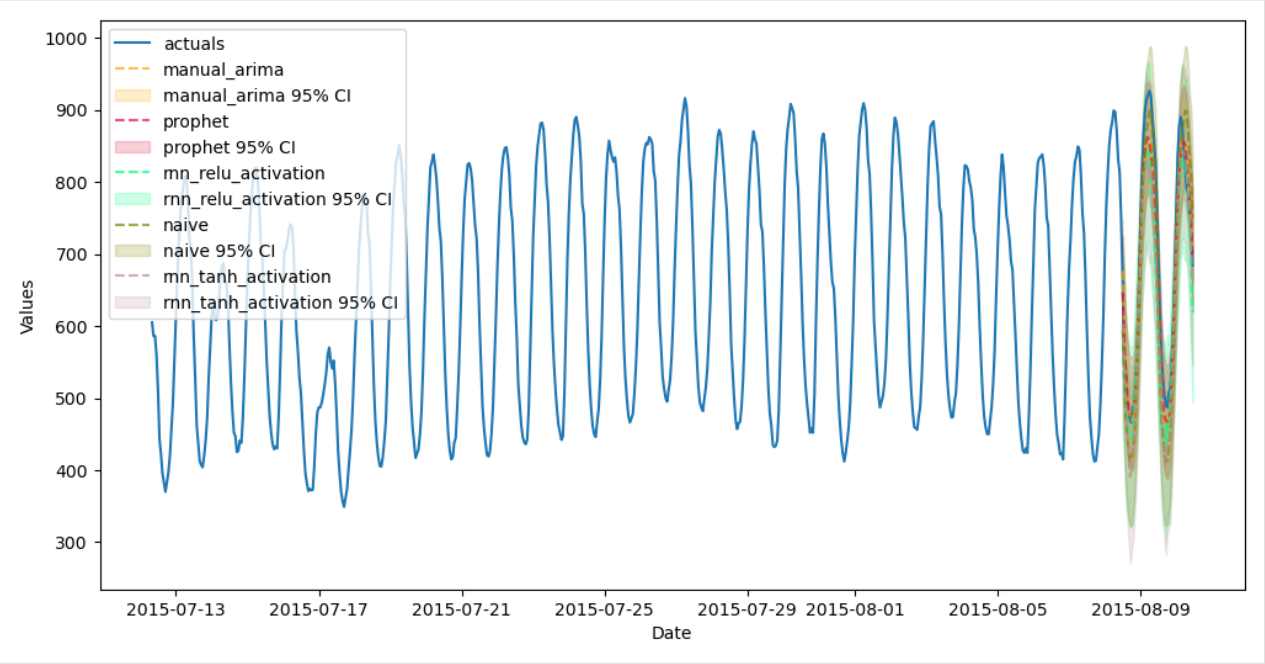
Using the last 48 observations in the `Forecaster` object to test each model, the arima model performed the best.

18.7 Plot Results

[15]:
```
f.plot(order_by="TestSetSMAPE",ci=True)
plt.show()
```



[16]:
```
f.plot_test_set(order_by="TestSetSMAPE",ci=True)
plt.show()
```



18.8 Stack Models

- To stack models in scalecast, you can either use the StackingRegressor from scikit-learn, or you can add the predictions from already-evaluated models into the `Forecaster` object using `Forecaster.add_signals()`. The latter approach is more advantageous as it can do everything that can be done with the StackingRegressor, but it can use non scikit-learn model classes, can more flexibly use other regressors, and is easier to tune.
- In the below example, we are using the signals generated from two LSTM models, an ARIMA model, a naive model, and Meta Prophet. We will also add the last 48 series lags to the object.
- One key point in the function below: we are specifying the `train_only` argument as False. This means that our test set will be compromised as we will introduce leakage from the other models. I chose to leave it False because this approach will ultimately be tested with a separate out-of-sample test set. The rule of thumb around this is to make this argument True if you want to report accurate test-set metrics but leave False when you want to deliver a Forecast into a future horizon. You can run this function twice with each option specified if you want to do both–run first time with `train_only=True`, evaluate models, and check the test-set metrics. Then, rerun with `train_only=False` and re-evaluate models to deliver future point predictions.

[17]:
```
f.add_ar_terms(48)
f.add_signals(
    f.history.keys(),
    #train_only = True, # uncomment to avoid leakage into the test set
)
f.set_estimator('catboost')
f
```

[17]:
```
Forecaster(
    DateStartActuals=2015-07-12T08:00:00.000000000
    DateEndActuals=2015-08-10T11:00:00.000000000
    Freq=H
```

(continues on next page)

(continued from previous page)

```
    N_actuals=700
    ForecastLength=48
    Xvars=['AR1', 'AR2', 'AR3', 'AR4', 'AR5', 'AR6', 'AR7', 'AR8', 'AR9', 'AR10', 'AR11',
↪ 'AR12', 'AR13', 'AR14', 'AR15', 'AR16', 'AR17', 'AR18', 'AR19', 'AR20', 'AR21', 'AR22
↪', 'AR23', 'AR24', 'AR25', 'AR26', 'AR27', 'AR28', 'AR29', 'AR30', 'AR31', 'AR32',
↪'AR33', 'AR34', 'AR35', 'AR36', 'AR37', 'AR38', 'AR39', 'AR40', 'AR41', 'AR42', 'AR43',
↪ 'AR44', 'AR45', 'AR46', 'AR47', 'AR48', 'signal_naive', 'signal_manual_arima',
↪'signal_rnn_tanh_activation', 'signal_rnn_relu_activation', 'signal_prophet']
    TestLength=48
    ValidationMetric=smape
    ForecastsEvaluated=['naive', 'manual_arima', 'rnn_tanh_activation', 'rnn_relu_
↪activation', 'prophet']
    CILevel=0.95
    CurrentEstimator=catboost
    GridsFile=Grids
)
```

Now we can train three catboost models: - One with all added regressors (the model signals and lags)
- One with just the model signals
- One with just the series lags

[18]:
```
f.manual_forecast(
    Xvars='all',
    call_me='catboost_all_reg',
    verbose = False,
)
f.save_feature_importance(method = 'shap') # it would be interesting to see the shapley␣
↪scores (later)
f.manual_forecast(
    Xvars=[x for x in f.get_regressor_names() if x.startswith('AR')],
    call_me = 'catboost_lags_only',
    verbose = False,
)
f.manual_forecast(
    Xvars=[x for x in f.get_regressor_names() if not x.startswith('AR')],
    call_me = 'catboost_signals_only',
    verbose = False,
)
```

[19]:
```
results = f.export(determine_best_by='TestSetSMAPE')
ms = results['model_summaries']
ms[
    [
        'ModelNickname',
        'TestSetLength',
        'TestSetSMAPE',
        'InSampleSMAPE',
    ]
]
```

[19]:

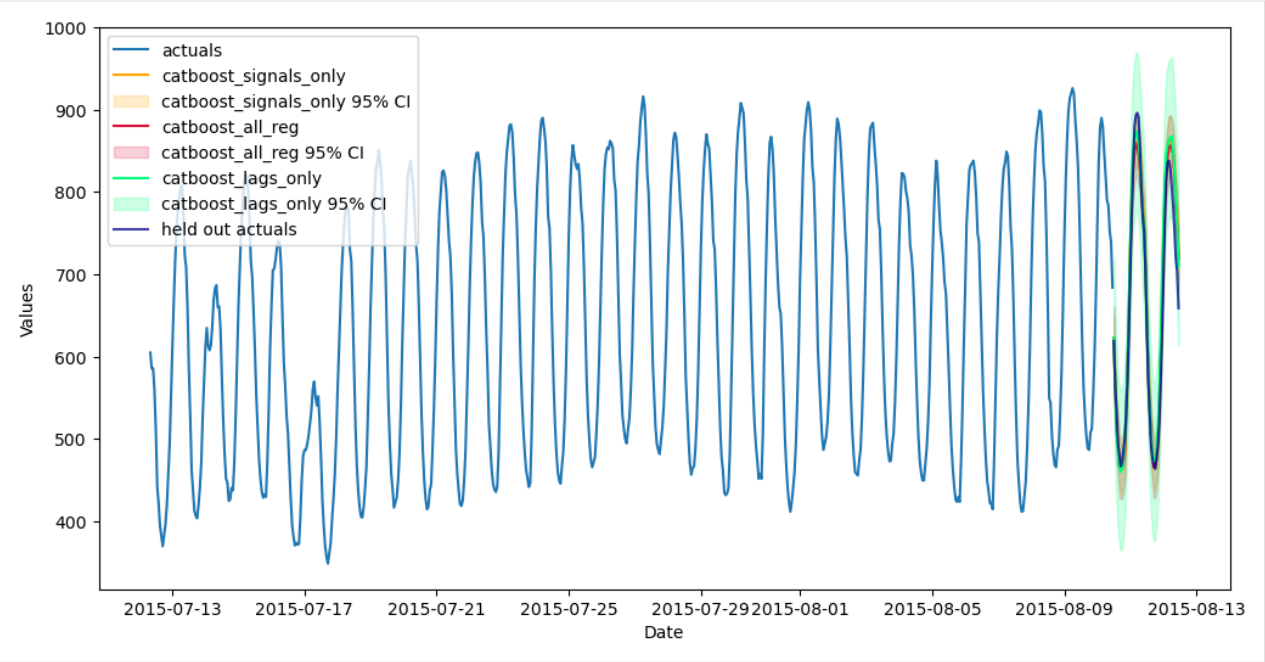
	ModelNickname	TestSetLength	TestSetSMAPE	InSampleSMAPE
0	catboost_signals_only	48	0.014934	0.007005
1	catboost_all_reg	48	0.022299	0.003340
2	manual_arima	48	0.046551	0.017995
3	prophet	48	0.047237	0.043859
4	catboost_lags_only	48	0.060460	0.003447
5	rnn_relu_activation	48	0.082511	0.081514
6	naive	48	0.093079	0.067697
7	rnn_tanh_activation	48	0.096998	0.059914

Unsuprisingly, now our catboost model with just the signals is showing the best test-set scores. But the test set has been compromised for all models that used signals as inputs. A way around that would have been to call `add_signals(train_only=True)`. Another way to really know how these models performed out-of-sample, we need to compare it with a separate out-of-sample test set.

18.9 Check Performance of Forecast on Held-Out Sample

[20]:

```
fig, ax = plt.subplots(figsize=(12,6))
f.plot(
    models = [m for m in f.history if m.startswith('catboost')],
    order_by="TestSetSMAPE",
    ci=True,
    ax = ax
)
sns.lineplot(
    x = f.future_dates,
    y = test_set,
    ax = ax,
    label = 'held out actuals',
    color = 'darkblue',
    alpha = .75,
)
plt.show()
```



[21]:
```
test_results = pd.DataFrame(index = f.history.keys(),columns = ['smape','mase'])
for k, v in f.history.items():
    test_results.loc[k,['smape','mase']] = [
        metrics.smape(test_set,v['Forecast']),
        metrics.mase(test_set,v['Forecast'],m=24,obs=f.y),
    ]

test_results.sort_values('smape')
```

[21]:

	smape	mase
catboost_all_reg	0.028472	0.47471
catboost_signals_only	0.029847	0.508708
rnn_tanh_activation	0.030332	0.482463
manual_arima	0.032933	0.542456
catboost_lags_only	0.035468	0.58522
prophet	0.039312	0.632253
naive	0.052629	0.827014
rnn_relu_activation	0.053967	0.844506

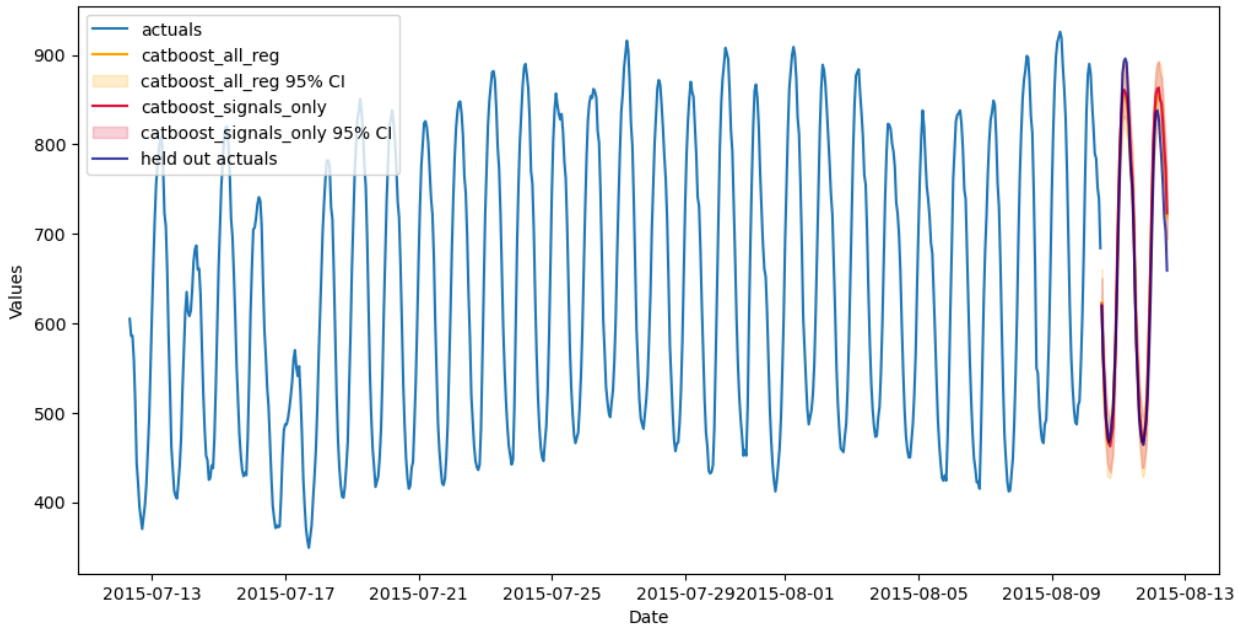
Now, we finally get to the crux of the analysis, where we can see that the catboost that used both the other model signals and the series lags performed best, followed by the catboost model that used only signals. This demonstrates the power of stacking and how it can make good models great.

[22]:
```
fig, ax = plt.subplots(figsize=(12,6))
f.plot(
    models = ['catboost_all_reg','catboost_signals_only'],
    ci=True,
    ax = ax
)
sns.lineplot(
    x = f.future_dates,
    y = test_set,
```

(continues on next page)

(continued from previous page)

```
    ax = ax,
    label = 'held out actuals',
    color = 'darkblue',
    alpha = .75,
)
plt.show()
```



18.10 View each covariate's shapley score

- Looking at the scores below, it is not surprising that the ARIMA signal was deemed the most important covariate in the final catboost model.

[23]:
```
f.export_feature_importance('catboost_all_reg')
```

[23]:

feature	weight	std
signal_manual_arima	43.409875	19.972339
AR1	23.524131	12.268015
signal_prophet	15.545415	7.210582

CHAPTER

NINETEEN

TRANSFER LEARNING

- This notebook shows how to use one fitted model stored in a `Forecaster` object to make predictions on a separate time series.
- Requires >=`0.19.0`
- As of `0.19.1`, univariate sklearn and tensorflow (RNN/LSTM) models are supported for this type of process. Multivariate sklearn, then the rest of the model types will be worked on next.
- See the documentation.

[1]:
```
from scalecast.Forecaster import Forecaster
from scalecast.util import infer_apply_Xvar_selection, find_optimal_transformation
from scalecast.Pipeline import Pipeline, Transformer, Reverter
from scalecast import GridGenerator
import pandas_datareader as pdr
import matplotlib.pyplot as plt
import pandas as pd
```

[2]:
```
GridGenerator.get_example_grids()
```

19.1 Initiate the First Forecaster Object

This series ends December, 2020.

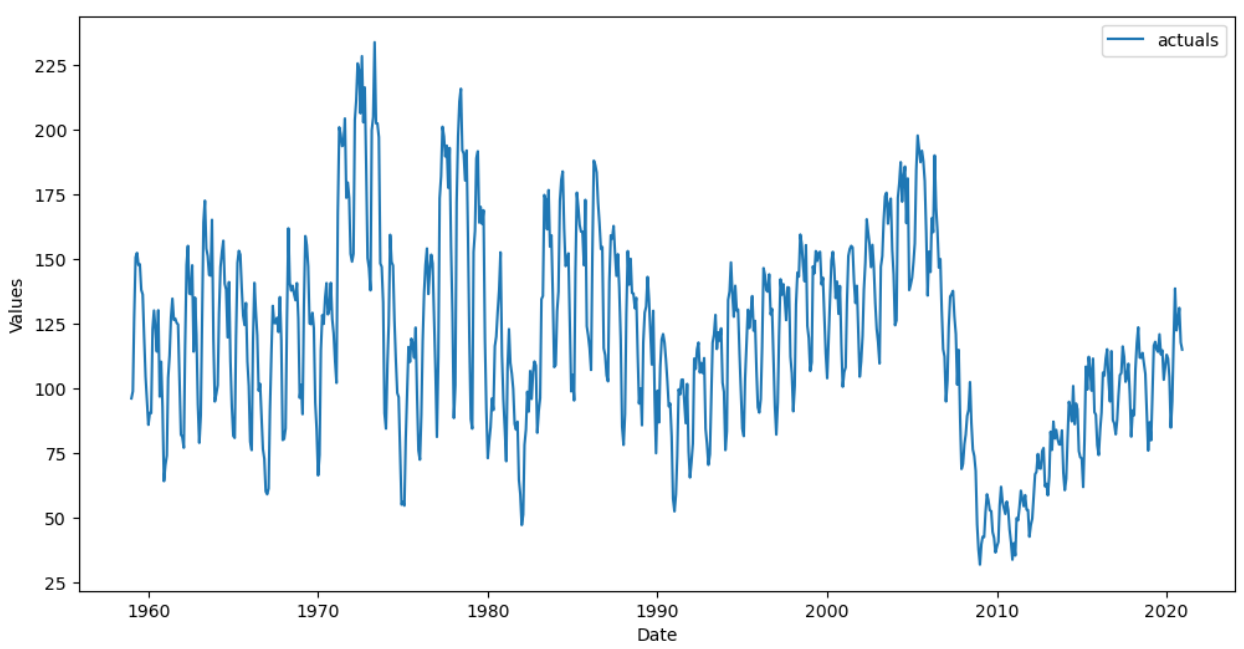
[3]:
```
df = pdr.get_data_fred(
    'HOUSTNSA',
    start = '1959-01-01',
    end = '2020-12-31',
)

df.tail()
```

[3]:
```
            HOUSTNSA
DATE
2020-08-01     122.5
2020-09-01     126.3
2020-10-01     131.2
2020-11-01     117.8
2020-12-01     115.1
```

[4]:
```
f = Forecaster(
    y = df.iloc[:,0],
    current_dates = df.index,
    future_dates = 24,
)

f.plot()
plt.show()
```



19.1.1 Automatically add Xvars to the object

[5]:
```
f.auto_Xvar_select()
f
```

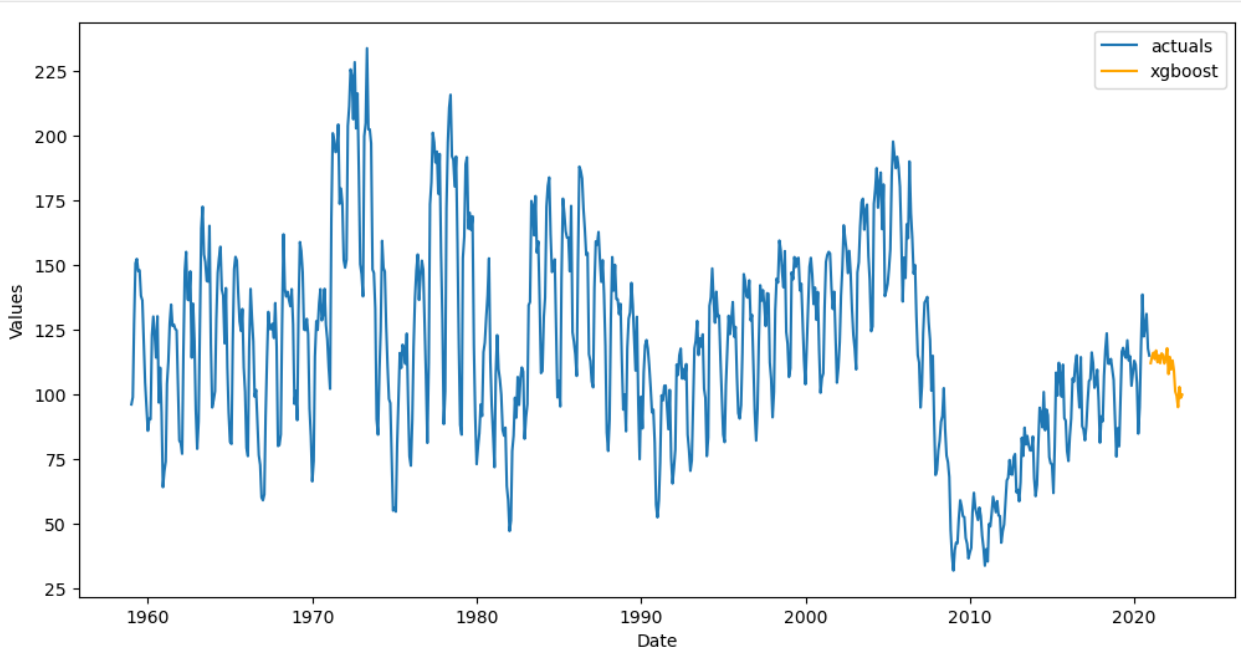
[5]:
```
Forecaster(
    DateStartActuals=1959-01-01T00:00:00.000000000
    DateEndActuals=2020-12-01T00:00:00.000000000
    Freq=MS
    N_actuals=744
    ForecastLength=24
    Xvars=['AR1', 'AR2', 'AR3', 'AR4']
    TestLength=0
    ValidationMetric=rmse
    ForecastsEvaluated=[]
    CILevel=None
    CurrentEstimator=mlr
    GridsFile=Grids
)
```

19.1.2 Fit an XGBoost Model and Make Predictions

[6]:
```
f.set_estimator('xgboost')
f.ingest_grid('xgboost')
f.limit_grid_size(10)
f.cross_validate(k=3,test_length=48)
f.auto_forecast()
```

19.1.3 View the Forecast

[7]:
```
f.plot()
plt.show()
```



19.2 Initiate the Second Forecaster Object

- Later, if we have more data streaming in, instead of refitting a model, we can use the already-fitted model to make the predictions. This updated series is through June, 2023
- You can use an updated version of the original series, you can use the same series with an extended Forecast horizon, or you can use an entirely different series (as long as it's the same frequency) to perform this process

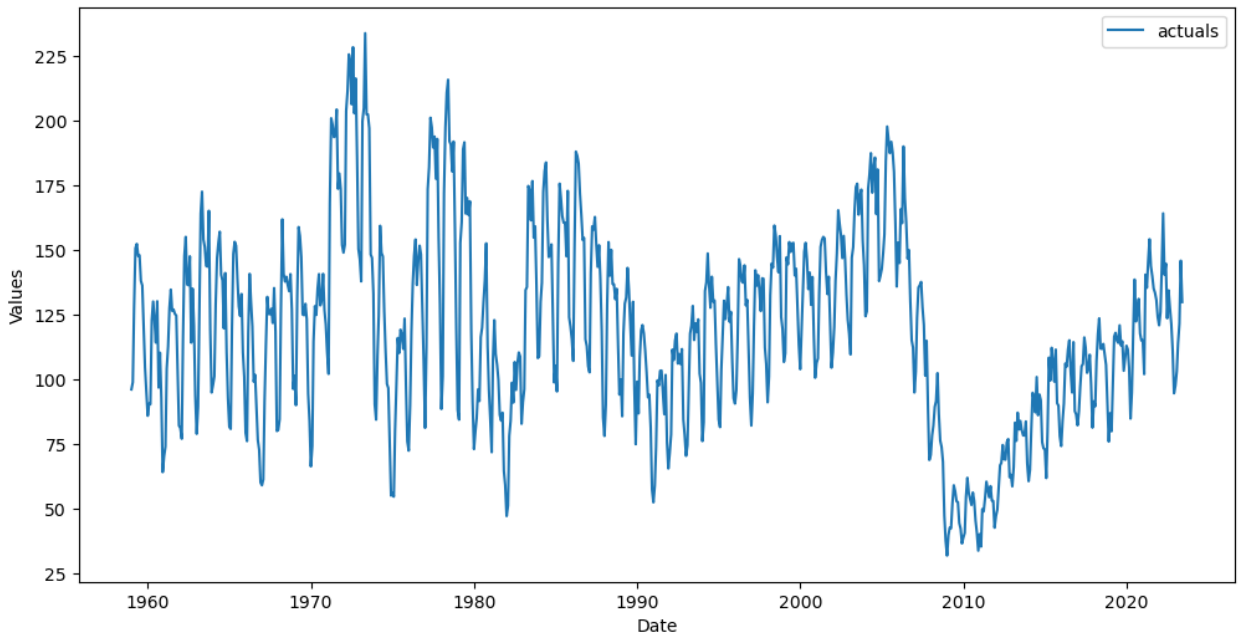
[8]:
```
df_new = pdr.get_data_fred(
    'HOUSTNSA',
    start = '1959-01-01',
    end = '2023-06-30',
)

df_new.tail()
```

[8]:
```
            HOUSTNSA
DATE
2023-02-01     103.2
2023-03-01     114.0
2023-04-01     121.7
2023-05-01     146.0
2023-06-01     130.0
```

[9]:
```
f_new = Forecaster(
    y = df_new.iloc[:,0],
    current_dates = df_new.index,
    future_dates = 48,
)

f_new.plot()
plt.show()
```



19.2.1 Add the same Xvars to the new Forecaster object

- The helper function below can assist when you automatically added Xvars
- If you manually added Xvars, you can wrap the selection process in a function and run this new `Forecaster` object through the same function.

[10]:
```
f_new = infer_apply_Xvar_selection(infer_from=f,apply_to=f_new)
f_new
```

[10]:
```
Forecaster(
    DateStartActuals=1959-01-01T00:00:00.000000000
    DateEndActuals=2023-06-01T00:00:00.000000000
    Freq=MS
```

(continues on next page)

(continued from previous page)

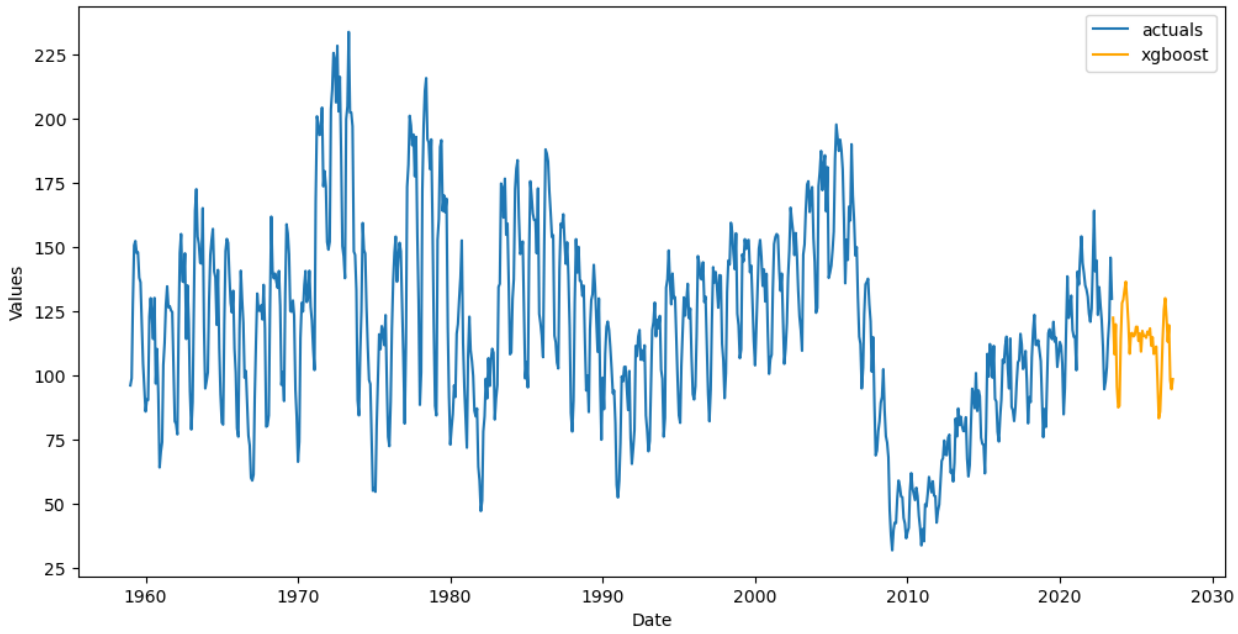
```
    N_actuals=774
    ForecastLength=48
    Xvars=['AR1', 'AR2', 'AR3', 'AR4']
    TestLength=0
    ValidationMetric=rmse
    ForecastsEvaluated=[]
    CILevel=None
    CurrentEstimator=mlr
    GridsFile=Grids
)
```

19.2.2 Apply fitted model from first object onto this new object

[11]:
```
f_new.transfer_predict(transfer_from=f,model='xgboost')
```

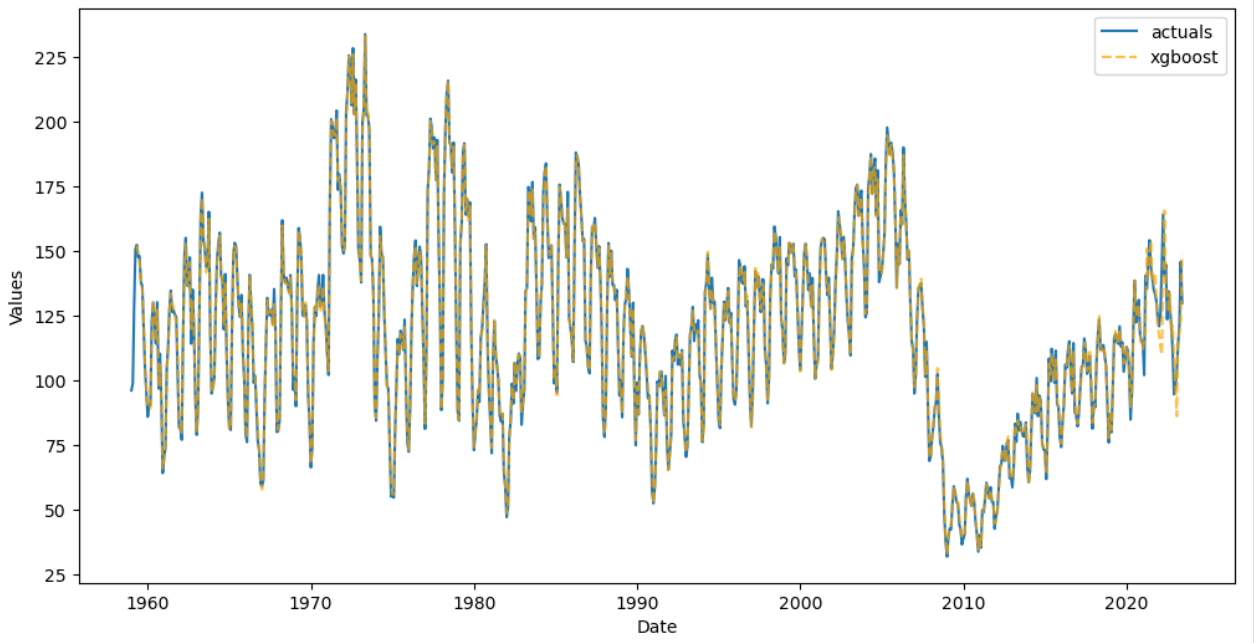
19.2.3 View the new forecast

[13]:
```
f_new.plot()
plt.show()
```



19.2.4 View the in-sample predictions

[14]:
```
f_new.plot_fitted()
plt.show()
```



In the below plot, the model has seen all observations until December, 2020. From January, 2021 through June, 2023, it is seeing those observations for the first time, but because it has the actual y observations, its predictions are expected to be more accurate than the forecast into the unknown horizon.

19.3 Predict over a specific date range

- Instead of storing the model info into the new `Forecaster` object, you can instead get predicted output over a specific date range.

[15]:
```
preds = f_new.transfer_predict(
    transfer_from = f,
    model = 'xgboost',
    dates = pd.date_range(start='2021-01-01',end='2023-12-31',freq='MS'),
    save_to_history=False,
    return_series=True,
)
preds
```

[15]:
```
2021-01-01    112.175186
2021-02-01    115.029518
2021-03-01    118.659706
2021-04-01    151.111618
2021-05-01    140.886765
2021-06-01    147.894882
2021-07-01    154.100571
2021-08-01    137.926544
```

(continues on next page)

(continued from previous page)

2022-01-01    117.764030
2022-02-01    112.886353
2022-03-01    110.008720
2022-04-01    139.413696
2022-05-01    165.805817
2022-06-01    135.017914
2022-07-01    134.379486
2022-08-01    126.559814
2022-09-01    133.788025
2022-10-01    118.278656
2022-11-01    121.269691
2022-12-01    110.270599
2023-01-01     98.168579
2023-02-01     86.210205
2023-03-01    115.844292
2023-04-01    118.449600
2023-05-01    123.620918
2023-06-01    148.793396
2023-07-01    122.571846
2023-08-01    108.331818
2023-09-01    120.023163
2023-10-01     95.729309
2023-11-01     87.593613
2023-12-01     88.265671
dtype: float32
```

From January through June, 2021, the predictions are considered in-sample, although the model has never previously seen them (it predicted using the actual y observations over that timespan, and that is a form of leakage for auto-regressive time series models). The rest of the predictions are truly out-of-sample.

19.4 Transfer Predict in a Pipeline

- We can use auto-transformation selection and pipelines to apply predictions from a fitted model into a new Forecaster object. This can be good to apply when new data frequently comes through and you don't want to refit models.

19.4.1 Find optimal set of transformations

[16]:
```
transformer, reverter = find_optimal_transformation(f,verbose=True)
```

```
Using xgboost model to find the best transformation set on 1 test sets, each 24 in␣
↪length.
All transformation tries will be evaluated with 12 lags.

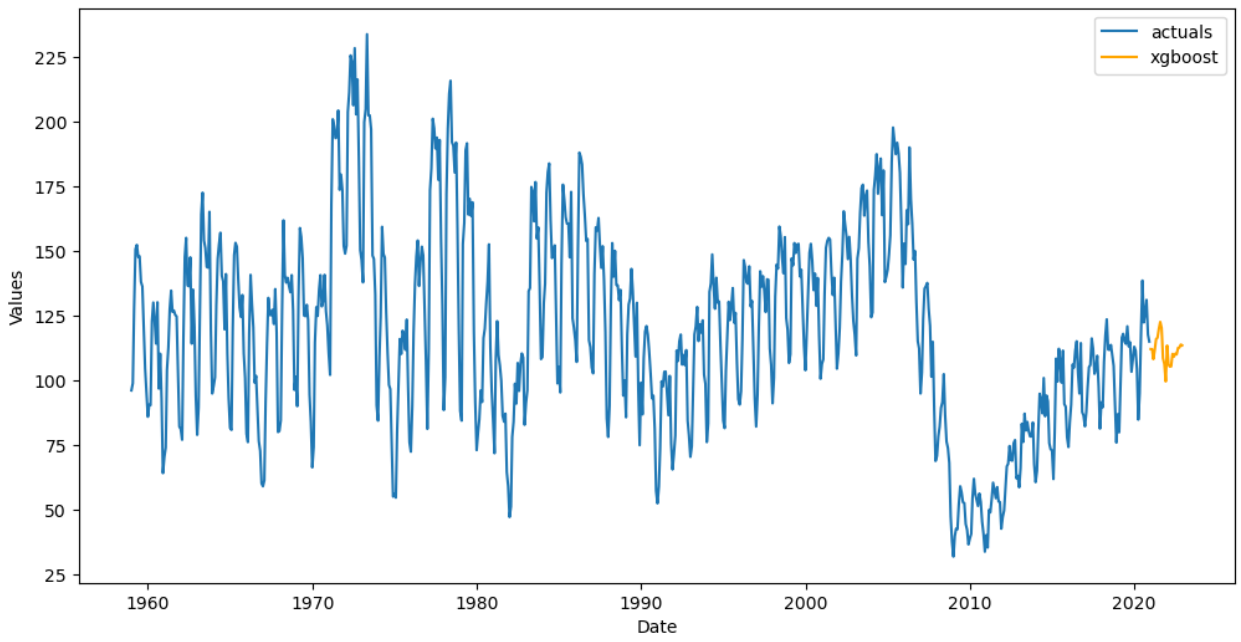
19.4.2 Fit the first pipeline

[17]:
```
def forecaster(f):
    f.auto_Xvar_select()
    f.ingest_grid('xgboost')
    f.limit_grid_size(10)
    f.cross_validate(k=3,test_length=48)
    f.auto_forecast()
```

[18]:
```
pipeline = Pipeline(
    steps = [
        ('Transform',transformer),
        ('Forecast',forecaster),
        ('Revert',reverter),
    ]
)

f = pipeline.fit_predict(f)
```

[19]:
```
f.plot()
plt.show()
```



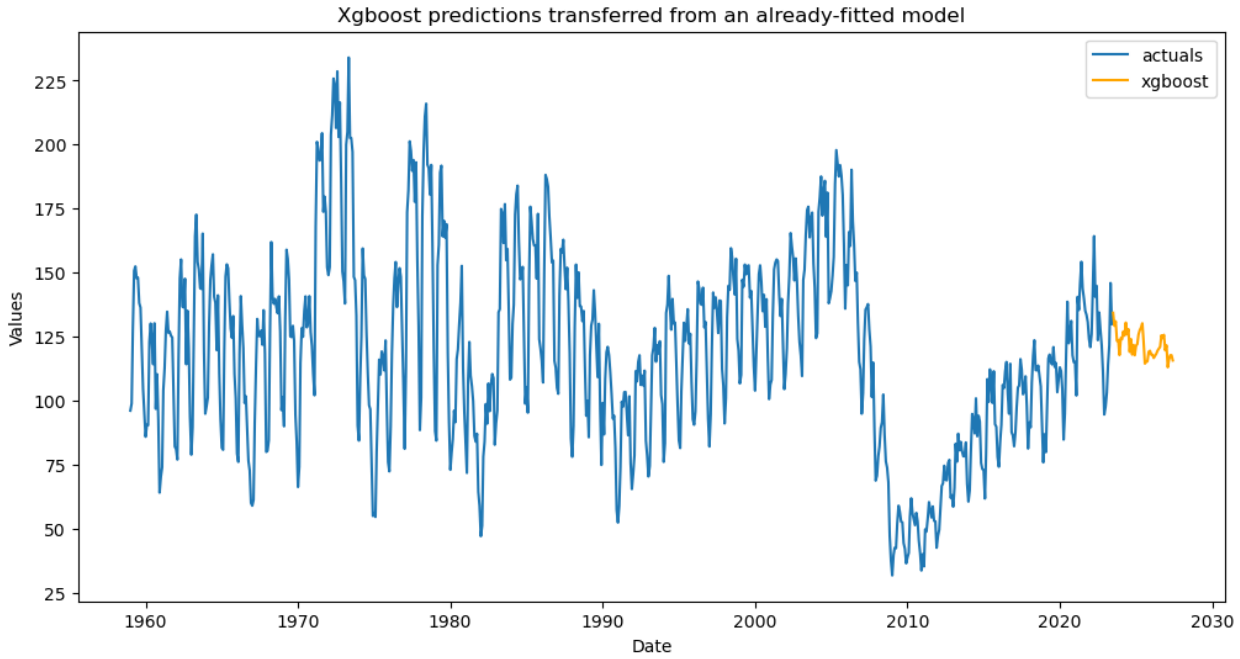
19.4.3 Predict new data

[20]:
```
def transfer_forecast(f,transfer_from):
    infer_apply_Xvar_selection(infer_from=transfer_from,apply_to=f)
    f.transfer_predict(transfer_from=transfer_from,model='xgboost')
```

[21]:
```
pipeline_new = Pipeline(
    steps = [
        ('Transform',transformer),
        ('Transfer Forecast',transfer_forecast),
        ('Revert',reverter),
    ]
)

f_new = pipeline_new.fit_predict(f_new,transfer_from=f) # even though it says fit, no␣
↪model actually gets fit in the pipeline
```

[23]:
```
f_new.plot()
plt.title('Xgboost predictions transferred from an already-fitted model')
plt.show()
```



[ ]:

CHAPTER

TWENTY

TRANSFER LEARNING - TENSORFLOW

- Transfer learning tensorflow (RNN/LSTM) models works slightly different than other model types, due to the difficulty of carrying these models in `Forecaster` object history. `Forecater` objects are meant to be be copied and pickled, both of which can fail with tensorflow models. For that reason, it is good to save out tensorflow models manually before using them to transfer learn.
- This notebook also demonstrates transferring confidence intervals.
- Requires >=`0.19.1`.

[1]:
```
from scalecast.Forecaster import Forecaster
from scalecast.util import infer_apply_Xvar_selection, find_optimal_transformation
from scalecast.Pipeline import Pipeline, Transformer, Reverter
from scalecast import GridGenerator
import pandas_datareader as pdr
import matplotlib.pyplot as plt
import pandas as pd
```

20.1 Initiate the First Forecaster Object

This series ends December, 2020.

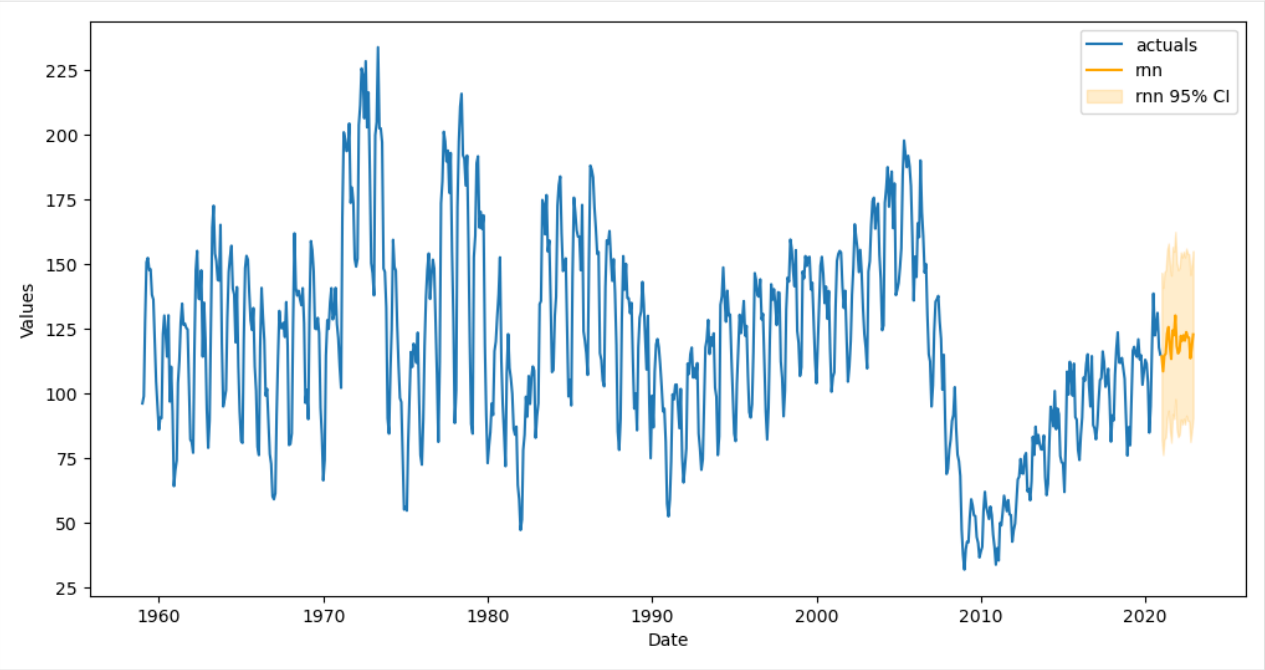
22/22 [==============================] - 0s 3ms/step
```

[5]:
```
f.plot(ci=True)
plt.show()
```



20.1.2 Save the model out

After you fit a tensforflow model, the fit model is attached to the `Forecaster` in the `tf_model` attribute. You can view the model summary:

[6]:
```
f.tf_model.summary()
```

```
Model: "sequential_1"
_________________________________________________________________
 Layer (type)                Output Shape              Param #
=================================================================
 simple_rnn_1 (SimpleRNN)    (None, 8)                 80

 dense_1 (Dense)             (None, 24)                216

=================================================================
Total params: 296
Trainable params: 296
Non-trainable params: 0
_________________________________________________________________
```

However, immediately after changing estimators or when the object is pickled out, this attribute is lost. Therefore, it is a good idea to save the model out:

[7]:
```
f.save_tf_model(name='model.h5') # default argument
```

Later, when you want to transfer learn with the model, you can re-attach it to the `Forecaster` object:

[8]:
```
f.load_tf_model(name='model.h5') # default argument
```

This re-attaches the `tf_model` attribute.

20.2 Initiate the Second Forecaster Object

- Later, if we have more data streaming in, instead of refitting a model, we can use the already-fitted model to make the predictions. This updated series is through June, 2023
- You can use an updated version of the original series, you can use the same series with an extended Forecast horizon, or you can use an entirely different series (as long as it's the same frequency) to perform this process

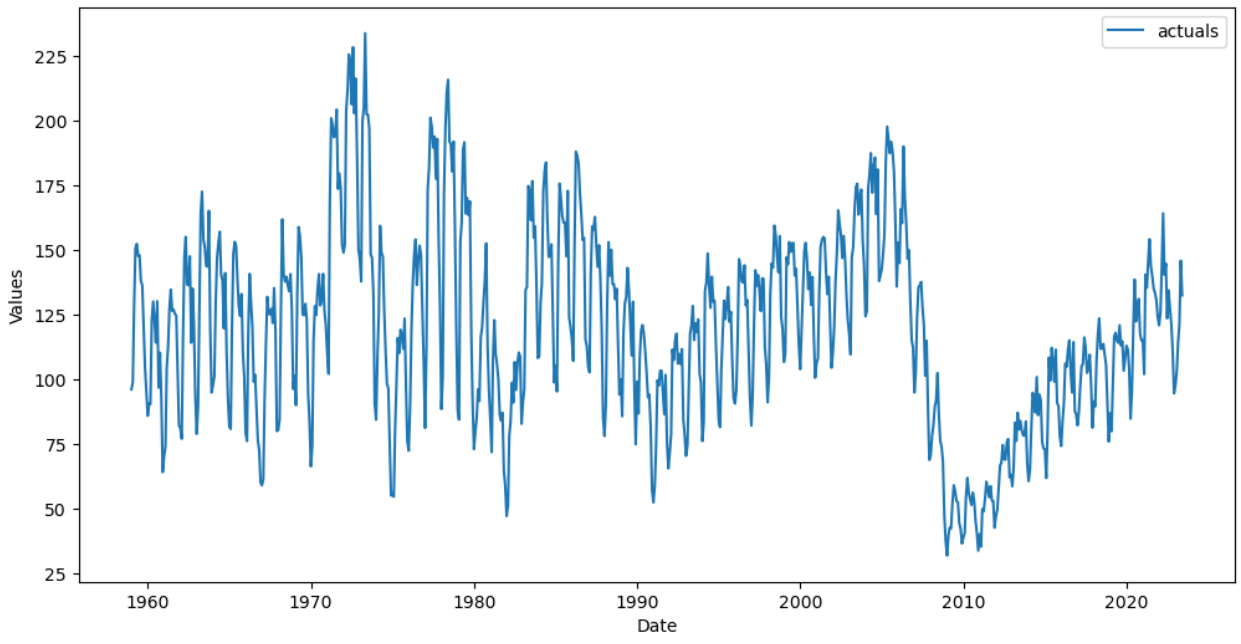
[9]:
```
df_new = pdr.get_data_fred(
    'HOUSTNSA',
    start = '1959-01-01',
    end = '2023-06-30',
)

df_new.tail()
```

[9]:
```
            HOUSTNSA
DATE
2023-02-01     103.2
2023-03-01     114.0
2023-04-01     121.7
2023-05-01     146.0
2023-06-01     132.6
```

[10]:
```
f_new = Forecaster(
    y = df_new.iloc[:,0],
    current_dates = df_new.index,
    future_dates = 24,
)

f_new.plot()
plt.show()
```



20.2.1 Add the same Xvars to the new Forecaster object

- The helper function below can assist when you automatically added Xvars
- If you manually added Xvars, you can wrap the selection process in a function and run this new `Forecaster` object through the same function.

[11]:
```
infer_apply_Xvar_selection(infer_from=f,apply_to=f_new)
```

[11]:
```
Forecaster(
    DateStartActuals=1959-01-01T00:00:00.000000000
    DateEndActuals=2023-06-01T00:00:00.000000000
    Freq=MS
    N_actuals=774
    ForecastLength=24
    Xvars=['AR1', 'AR2', 'AR3', 'AR4', 'AR5', 'AR6', 'AR7', 'AR8', 'AR9', 'AR10', 'AR11',
↪ 'AR12', 'AR13', 'AR14', 'AR15', 'AR16', 'AR17', 'AR18', 'AR19', 'AR20', 'AR21', 'AR22
↪', 'AR23', 'AR24']
    TestLength=0
    ValidationMetric=rmse
    ForecastsEvaluated=[]
    CILevel=None
    CurrentEstimator=mlr
    GridsFile=Grids
)
```

20.2.2 Apply fitted model from first object onto this new object

[12]:
```
f_new.transfer_predict(transfer_from=f,model='rnn',model_type='tf')
```

```
1/1 [==============================] - 0s 149ms/step
23/23 [==============================] - 0s 2ms/step
```

20.2.3 Transfer the model's confidence intervals

[13]:
```
f_new.transfer_cis(transfer_from=f,model='rnn') # transfer the model's confidence␣
↪intervals
```

[14]:
```
f_new.plot(ci=True)
plt.show()
```

TWENTYONE

TRANSFORMATIONS EXAMPLE

- This is the accompanying code to the medium publication.
- See the documentation for SeriesTransformer, Transformer, and Reverter.

[1]:
```
import pandas as pd
import matplotlib.pyplot as plt
from scalecast.Forecaster import Forecaster
from scalecast.SeriesTransformer import SeriesTransformer
```

[2]:
```
data = pd.read_csv('../lstm/AirPassengers.csv')
```

[3]:
```
data.head()
```

[3]:
```
     Month  #Passengers
0  1949-01          112
1  1949-02          118
2  1949-03          132
3  1949-04          129
4  1949-05          121
```

[4]:
```
f = Forecaster(
    current_dates = data['Month'],
    y = data['#Passengers'],
    future_dates = 24,
)
```

21.1 Create Thumbnail Image

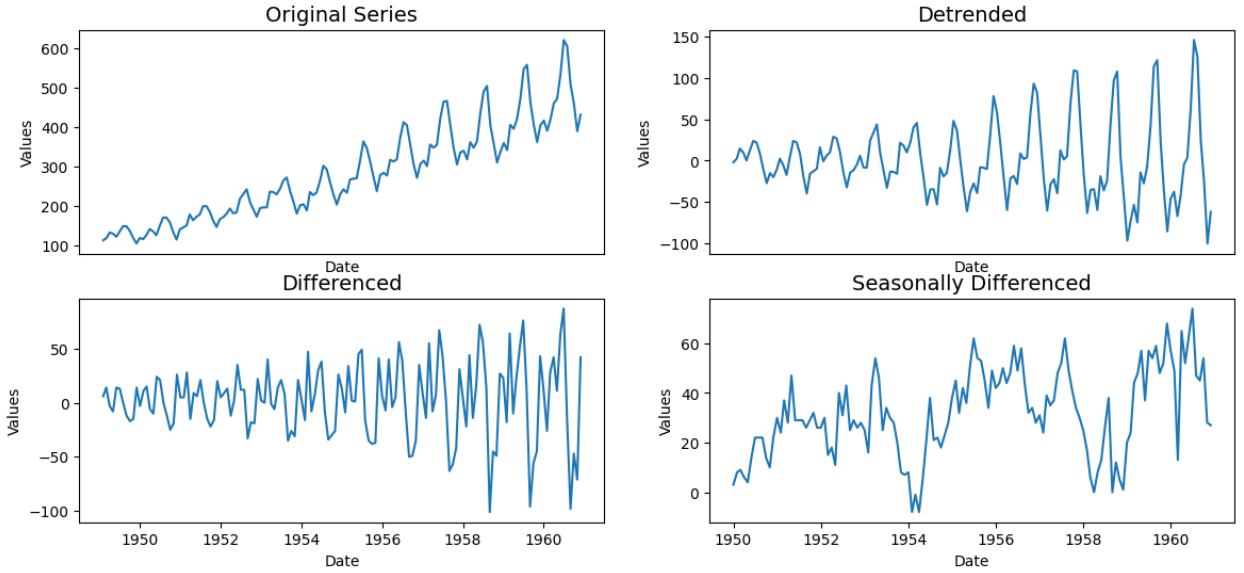
[5]:
```
f_detrended = SeriesTransformer(f).DetrendTransform(poly_order=2)
f_diff = SeriesTransformer(f).DiffTransform()
f_diff_seas = SeriesTransformer(f).DiffTransform(12)
```

[6]:
```
fig, axs = plt.subplots(2,2,figsize=(14,6))
f.plot(ax=axs[0,0])
axs[0,0].set_title('Original Series',size=14)
axs[0,0].tick_params(axis='x',which='both',bottom=False,top=False,labelbottom=False)
axs[0,0].get_legend().remove()
f_detrended.plot(ax=axs[0,1])
```

(continues on next page)

(continued from previous page)

```
axs[0,1].set_title('Detrended',size=14)
axs[0,1].tick_params(axis='x',which='both',bottom=False,top=False,labelbottom=False)
axs[0,1].get_legend().remove()
f_diff.plot(ax=axs[1,0])
axs[1,0].set_title('Differenced',size=14)
axs[1,0].get_legend().remove()
f_diff_seas.plot(ax=axs[1,1])
axs[1,1].set_title('Seasonally Differenced',size=14)
axs[1,1].get_legend().remove()
plt.show()
```

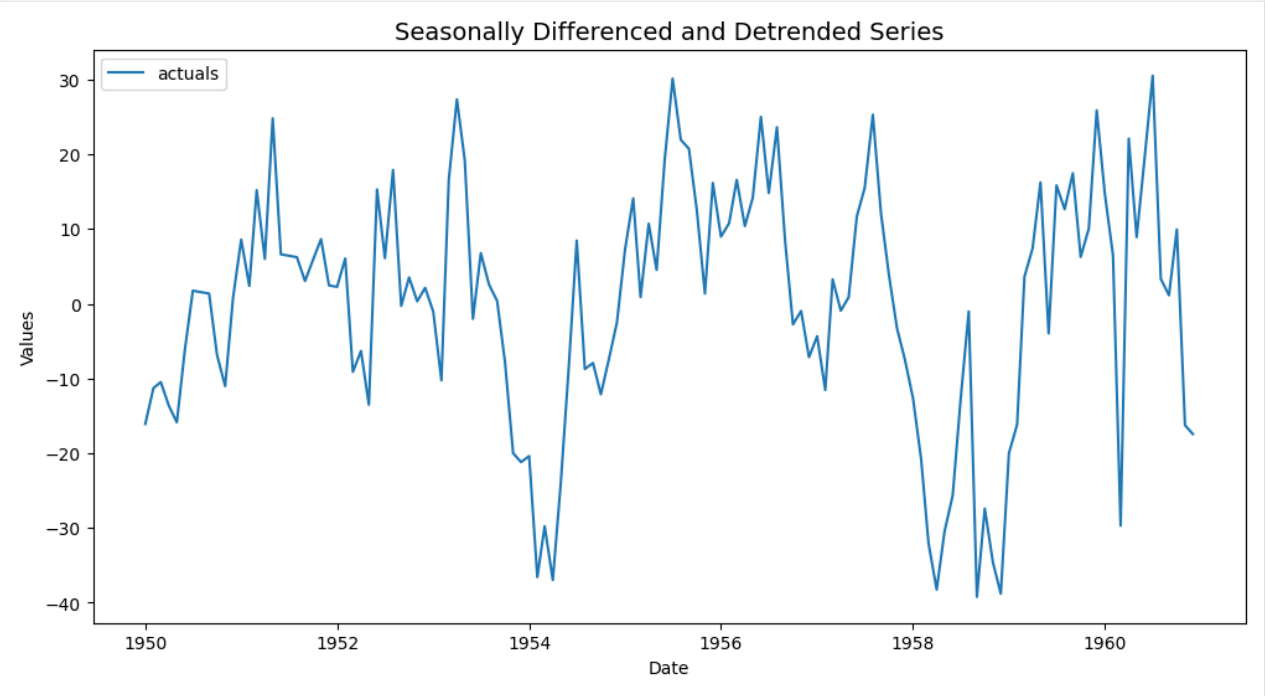


21.2 Create Transformer

[7]:
```
transformer = SeriesTransformer(f)
```

21.3 Apply Transformations

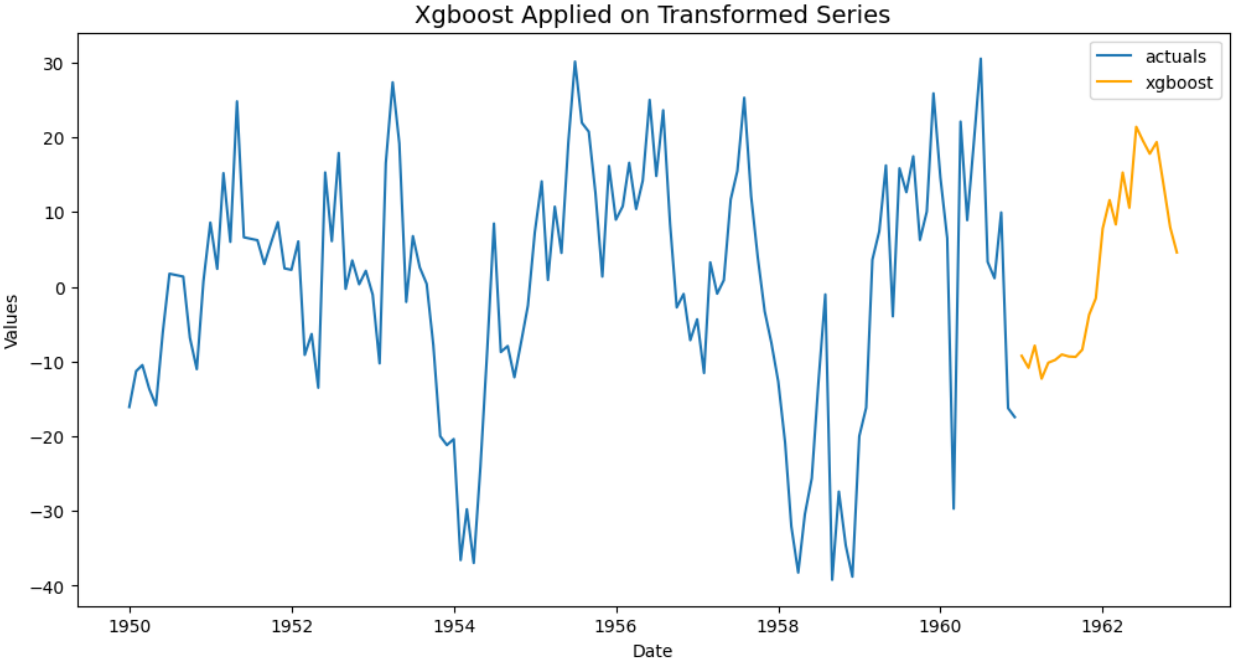
[8]:
```
f = transformer.DiffTransform(12) # 12 periods is one seasonal difference for monthly␣
↪data
f = transformer.DetrendTransform()
f.plot()
plt.title('Seasonally Differenced and Detrended Series',size=14);
```



21.4 Forecast on Transformed Data

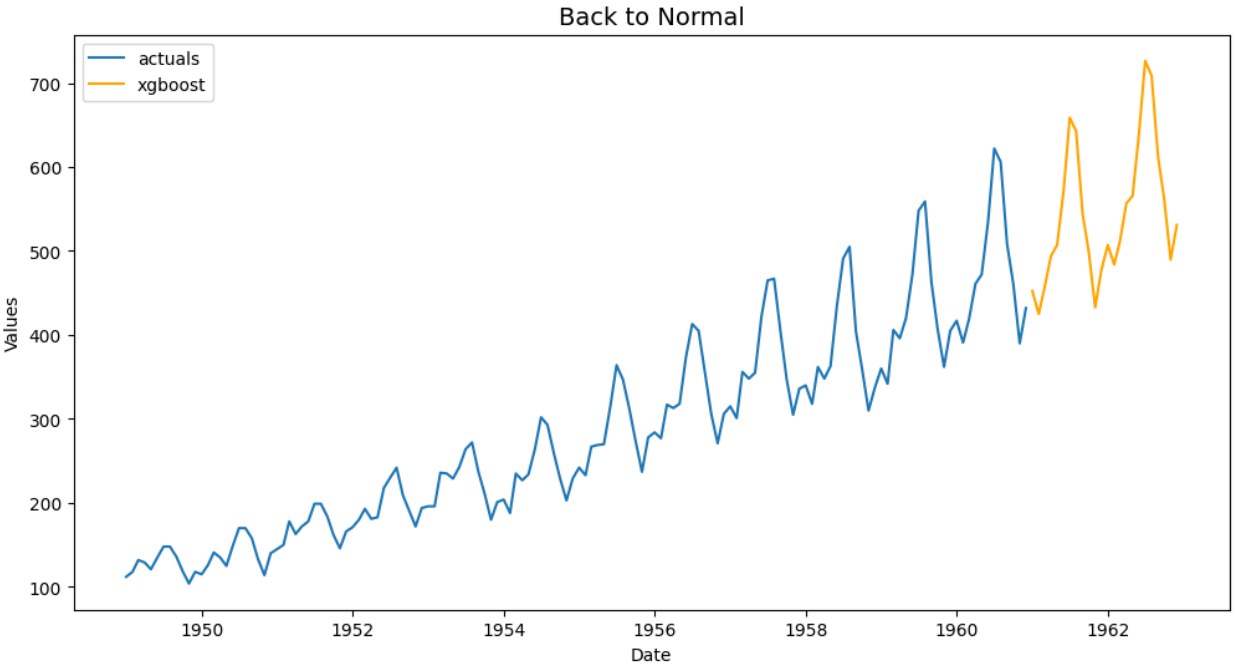
[9]:
```
f.set_estimator('xgboost')
f.add_ar_terms(12)
f.manual_forecast(n_estimators=100,gamma=2)
```

[10]:
```
f.plot()
plt.title('Xgboost Applied on Transformed Series',size=14);
```



21.5 Revert Transformation

[11]:
```
f = transformer.DetrendRevert()
f = transformer.DiffRevert(12)
f.plot()
plt.title('Back to Normal',size=14);
```



Note: After reverting a difference transforamtion, it is a good idea to drop all Xvars from the object and re-add them, especially model lags, since their values are now at a different level and they will have lost some observations from the front.

[12]:
```
f.drop_all_Xvars()
```

21.6 Function to Automatically Find Optimal Transformation

- Documentation

[13]:
```
from scalecast.util import find_optimal_transformation
# default args below
transformer, reverter = find_optimal_transformation(
    f, # Forecaster object to try the transformations on
    estimator=None, # model used to evaluate each transformation, default last estimator␣
↪set in object
    monitor='rmse', # out-of-sample metric to monitor
    test_length = None, # default is the fcst horizon in the Forecaster object
    train_length = None, # default is the max available
    num_test_sets = 1, # number of test sets to iterate through, final transformation␣
↪based on best avg. metric
    space_between_sets = 1, # space between consectutive train sets
    lags='auto', # uses the length of the inferred seasonality
    try_order = ['detrend','seasonal_adj','boxcox','first_diff','first_seasonal_diff',
↪'scale'], # order of transformations to try
    boxcox_lambdas = [-0.5,0,0.5], # box-cox lambas
    detrend_kwargs = [{'loess': True},{'poly_order':1},{'poly_order':2}], # detrender␣
↪transform kwargs (tries as many detrenders as the length of this list)
    scale_type = ['Scale','MinMax'], # scale transformers to try
    m = 'auto', # the seasonal length to try for the seasonal adjusters, accepts multiple
    model = 'add', # the model to use when seasonally adjusting
    verbose = True, # default is False
    # specific model kwargs also accepted
)
```

```

21.7 Automated Forecasting with Pipeline

[14]:
```
from scalecast.Pipeline import Pipeline
from scalecast import GridGenerator
from scalecast.util import find_optimal_transformation

GridGenerator.get_example_grids()

def forecaster(f):
    f.set_validation_length(20)
    f.auto_Xvar_select(max_ar=20)
    f.tune_test_forecast(
        ['elasticnet','xgboost'],
        cross_validate=True,
        limit_grid_size = .2,
    )

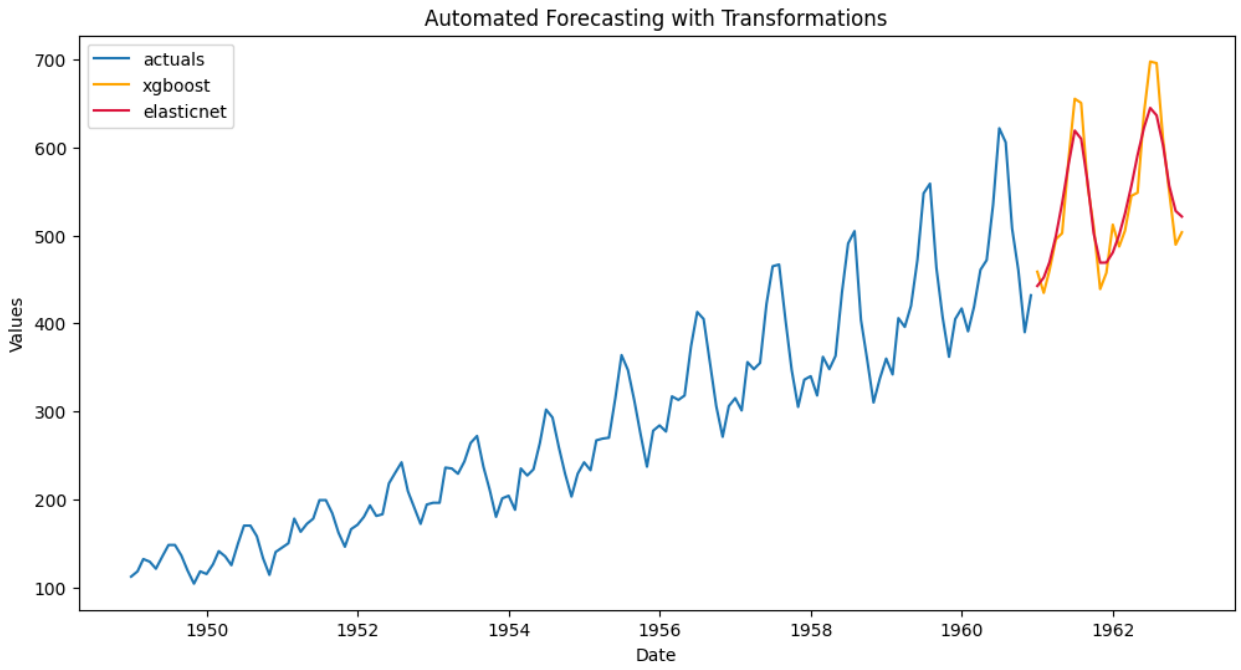
pipeline = Pipeline(
    steps = [
        ('Transform',transformer),
        ('Forecast',forecaster),
        ('Revert',reverter),
    ],
)

f = pipeline.fit_predict(f)
```

(continues on next page)

(continued from previous page)

```
f.plot()
plt.title('Automated Forecasting with Transformations');
```



```

TWENTYTWO

THETA

- Read about the theta model
- See the darts implementation
- See the statsmodels implementation
- Download data from GitHub
- Install darts: `pip install darts`
- See the blog post

Scalecast ports the model from darts, which is supposed to be more accurate and is also easier to maintain.

[1]:
```
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
import seaborn as sns
from scipy import stats
from darts.utils.utils import SeasonalityMode, TrendMode, ModelMode
from scalecast.Forecaster import Forecaster
from scalecast.util import metrics
from scalecast import GridGenerator
```

[2]:
```
train = pd.read_csv('Hourly-train.csv',index_col=0)
test = pd.read_csv('Hourly-test.csv',index_col=0)
y = train.loc['H7'].to_list()
current_dates = pd.date_range(start='2015-01-07 12:00',freq='H',periods=len(y)).to_list()

y_test = test.loc['H7'].to_list()

f = Forecaster(
    y=y,
    current_dates=current_dates,
    metrics = ['smape','r2'],
    test_length = .25,
    future_dates = len(y_test),
    cis = True,
)

f
```

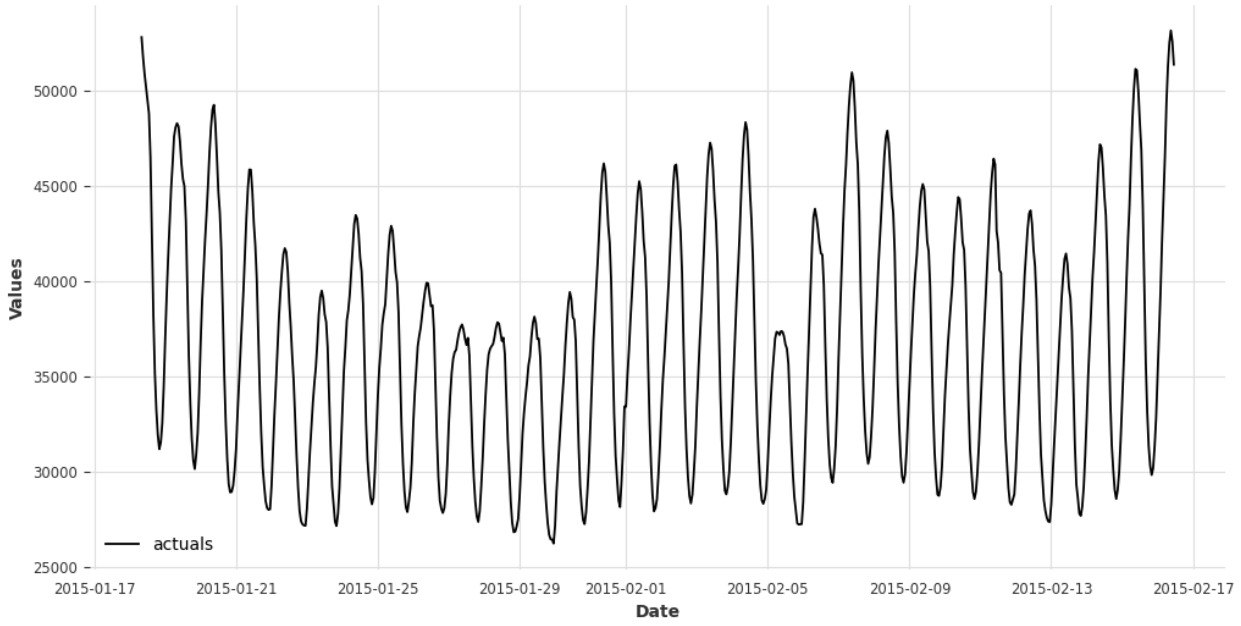
[2]:
```
Forecaster(
    DateStartActuals=2015-01-18T08:00:00.000000000
```

(continues on next page)

(continued from previous page)

```
    DateEndActuals=2015-02-16T11:00:00.000000000
    Freq=H
    N_actuals=700
    ForecastLength=48
    Xvars=[]
    TestLength=240
    ValidationMetric=smape
    ForecastsEvaluated=[]
    CILevel=0.95
    CurrentEstimator=mlr
    GridsFile=Grids
)
```

[3]:
```
f.plot()
plt.show()
```



22.1 Prepare forecast

- Download theta's validation grid

[6]:
```
GridGenerator.get_grids('theta',out_name='Grids.py')
f.ingest_grid('theta')
```

22.2 Call the forecast

- tune hyperparemters with 3-fold time series cross validation

[8]:
```
f.set_estimator('theta')
f.cross_validate(k=3,verbose=True)
f.auto_forecast()
```

```
Num hyperparams to try for the theta model: 48.
Fold 0: Train size: 345 (2015-01-18 08:00:00 - 2015-02-01 16:00:00). Test Size: 115␣
↪(2015-02-01 17:00:00 - 2015-02-06 11:00:00).
Fold 1: Train size: 230 (2015-01-18 08:00:00 - 2015-01-27 21:00:00). Test Size: 115␣

CHAPTER

TWENTYTHREE

VALIDATION

There are many ways to validate a model with scalecast and this notebook introduces them and overviews the differences between dynamic and non-dynamic tuning/testing, cross-validation, backtesting, and the eye test.

- Download data: https://www.kaggle.com/robervalt/sunspots
- See here for EDA on this dataset: https://scalecast-examples.readthedocs.io/en/latest/rnn/rnn.html
- See here for documentation on cross validation: https://scalecast.readthedocs.io/en/latest/Forecaster/Forecaster.html#src.scalecast.F

[1]:
```
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
import seaborn as sns
from scalecast.Forecaster import Forecaster
import diagram_creator
```

[2]:
```
def prepare_fcst(f, test_length=0.1, fcst_length=120):
    """ adds all variables and sets the test length/forecast length in the object

    Args:
        f (Forecaster): the Forecaster object.
        test_length (int or float): the test length as a size or proportion.
        fcst_length (int): the forecast horizon.

    Returns:
        (Forecaster) the processed object.
    """
    f.generate_future_dates(fcst_length)
    f.set_test_length(test_length)
    f.set_validation_length(f.test_length)
    f.eval_cis()
    f.add_seasonal_regressors("month")
    for i in np.arange(60, 289, 12):  # 12-month cycles from 12 to 288 months
        f.add_cycle(i)
    f.add_ar_terms(120)  # AR 1-120
    f.add_AR_terms((20, 12))  # seasonal AR up to 20 years, spaced one year apart
    f.add_seasonal_regressors("year")
    #f.auto_Xvar_select(irr_cycles=[120],estimator='gbt')
    return f

def export_results(f):
```

(continues on next page)

(continued from previous page)

```
    """ returns a dataframe with all model results given a Forecaster object.

    Args:
        f (Forecaster): the Forecaster object.

    Returns:
        (DataFrame) the dataframe with the pertinent results.
    """
    results = f.export("model_summaries", determine_best_by="TestSetMAE")
    return results[
        [
            "ModelNickname",
            "TestSetRMSE",
            "InSampleRMSE",
            "ValidationMetric",
            "ValidationMetricValue",
            "HyperParams",
            "TestSetLength",
            "DynamicallyTested",
        ]
    ]
```

23.1 Load Forecaster Object

- we choose 120 periods (10 years) for all validation and forecasting
- 10 years of observervations to tune model hyperparameters, 10 years to test, and a forecast horizon of 10 years

[3]:
```

```

[4]:
```
f.set_estimator('gbt')
```

In the feature_selection notebook, gbt was chosen as the best model class out of several tried. We will show all examples with this estimator.

23.2 Default Model Parameters

- one with dynamic testing
- one with non-dynamic testing
- the difference can be expressed by taking the case of a simple autoregressive model, such that:

23.2.1 Non-Dynamic Autoregressive Predictions

$$x_t = \alpha * x_{t-1} + e_t$$

Over an indefinite forecast horizon, the above equation would only work if you knew the value for x_{t-1}. Going more than one period into the future, you would stop knowing what that value is. In a test-set of data, of course, you do know all values into the forecast horizon, but to be more realistic, you could write an equation for a two-step forecast like this:

23.2.2 Dynamic Autoregressive Predictions

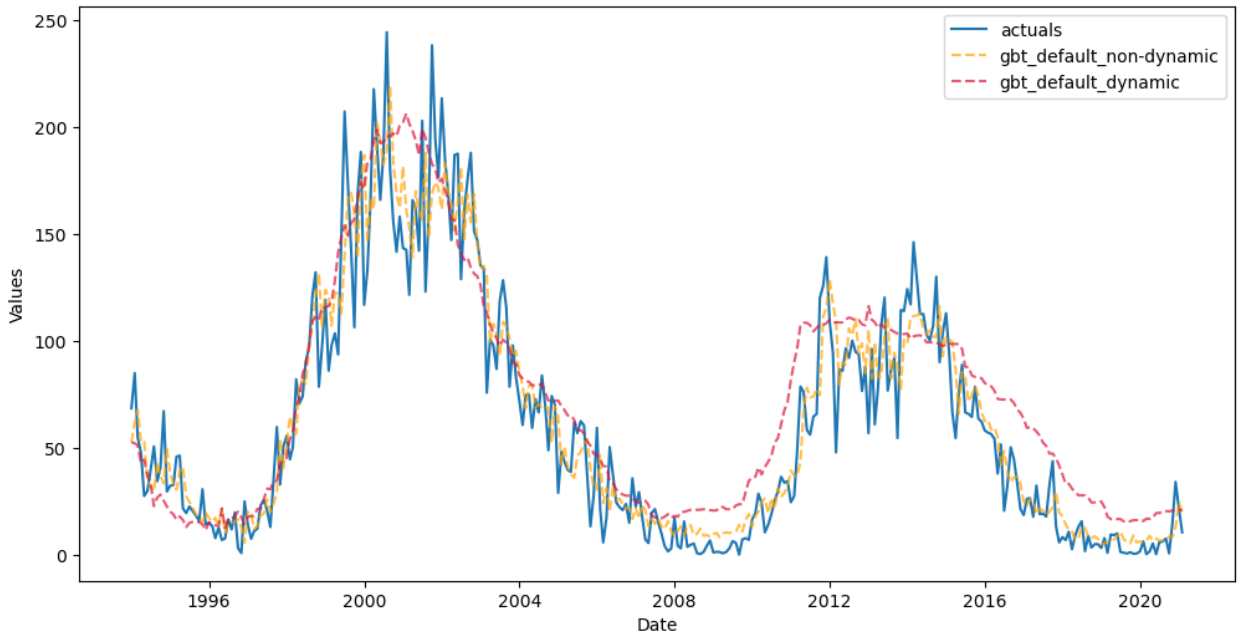
$$\hat{x_t} = \hat{\alpha} * x_{t-1}$$

$$x_{t+1} = \hat{\alpha} * \hat{x}_t + e_{t+1}$$

Using these two equations, which scalecast refers to as dynamic forecasting, you could evaluate any forecast horizon by plugging in predicted values for x_{t-1} or x_t over periods in which you did not know it. This is default behavior for all models tested through scalecast, but it is not default for tuning models. We will explore dynamic tuning soon. First, let's see in practical terms the difference between non-dynamic and dynamic testing.

[5]:
```
f.manual_forecast(call_me="gbt_default_non-dynamic", dynamic_testing=False)
f.manual_forecast(call_me="gbt_default_dynamic")  # default is dynamic testing
```

[6]:
```
f.plot_test_set(
    models=[
        "gbt_default_non-dynamic",
        "gbt_default_dynamic"
    ],
    include_train=False,
)
plt.show()
```



It appears that the non-dynamically tested model performed significantly better than the other, but looks can be deceiving. In essence, the non-dynamic model was only tested for its ability to perform 326 one-step forecasts and its final metric is an average of these one-step forecasts. It could be a good idea to set `dynamic_testing=False` if you want to speed up the testing process or if you only care about how your model would perform one step into the future. But to report the test-set metric from this model as if it could be expected to do that well for the full 326 periods into the future is misleading. The other model that was dynamically tested can be more realistically trusted in that regard.

[7]:
```
export_results(f)
```

[7]:

	ModelNickname	TestSetRMSE	InSampleRMSE	ValidationMetric	ValidationMetricValue	HyperParams	TestSetLength	DynamicallyTested
0	gbt_default_non-dynamic	18.723179	18.841544	NaN	NaN	{}	326	False
1	gbt_default_dynamic	24.456923	18.841544	NaN	NaN	{}	326	True

23.3 Tune the model to find optimal hyperparameters

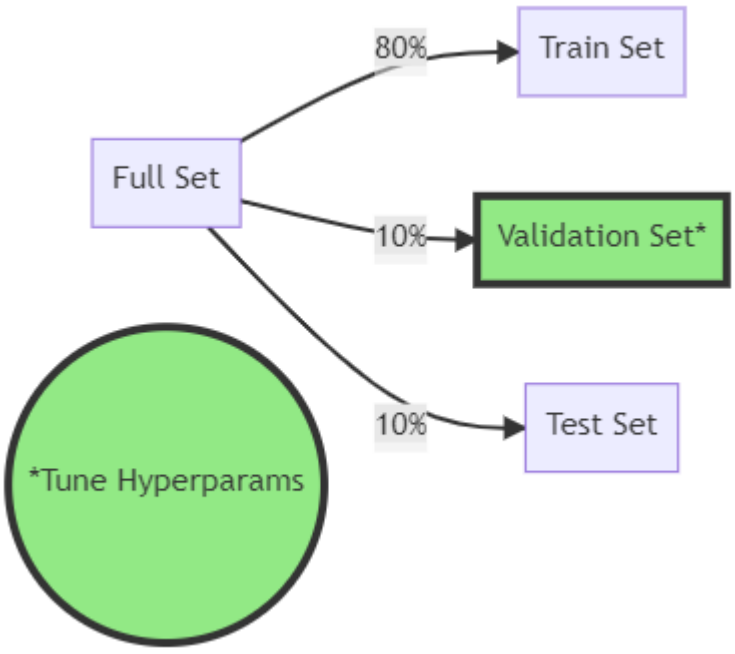
- Create a validation grid
- Try three strategies to tune the parameters:
- Train/validation/test split
  - Hyperparameters are tried on the validation set
- Train/test split with 5-fold time-series cross-validation on training set
  - Training data split 5 times into train/validations set
  - Models trained on training set only
  - Validated out-of-sample
  - All data available before each validation split sequentially used to train the model
- Train/test split with 5-fold time-series rolling cross-validation on training set
  - Rolling is different in that each train/validation split is the same size

[8]:
```
grid = {
    "max_depth": [2, 3, 5],
    "max_features": ["sqrt", "auto"],
    "subsample": [0.8, 0.9, 1],
}
```

[9]:
```
f.ingest_grid(grid)
```

23.3.1 Train/Validation/Test Split

- The data's sequence is always maintained in time-series splits with scalecast



[10]:
```
f.tune(dynamic_tuning=True)
f.auto_forecast(
    call_me="gbt_tuned"
)  # automatically uses optimal paramaeters suggested from the tuning process
```

[11]:
```
f.export_validation_grid("gbt_tuned").sort_values('AverageMetric').head(10)
```

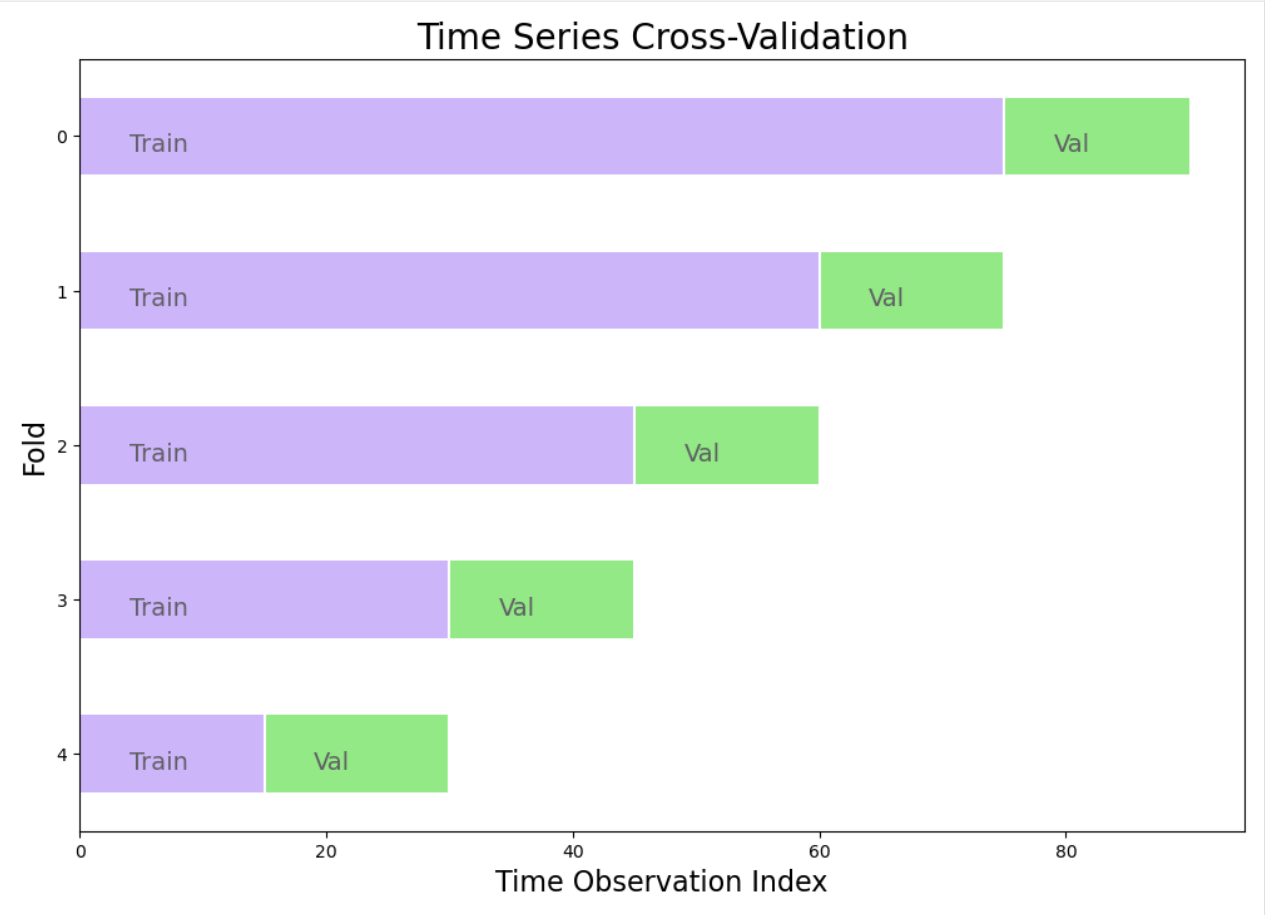
23.3.2 5-Fold Time Series Cross Validation

- Split training set into k (5) folds
- Each validation set is the same size and determined such that: `val_size = n_obs // (folds + 1)`
- The last training set will be the same size or almost the same size as the validation sets
- Model trained and re-trained with all data that came before each validation slice
- Each fold tested out of sample on its validation set
- Final error is an average of the out-of-sample error obtained from each fold
- The chosen hyperparameters are determined by which final error was minimized
- Below is an example with a dataset sized 100 observations and in which 10 observations are held out for testing and the remaining 90 observations are used as the training set:

[12]:
```
diagram_creator.create_cv()
```



The final error, E, can be expressed as an average of the error from each fold i:

$$E = \frac{1}{n}\sum_{i=0}^{n-1}(e_i)$$

[13]:
```
f.cross_validate(
    k=5,
    dynamic_tuning=True,
    test_length = None, # default so that last test and train sets are same size (or␣
↪close to the same)
    train_length = None, # default uses all observations before each test set
    space_between_sets = None, # default adds a length equal to the test set between␣
↪consecutive sets
    verbose = True, # print out info about each fold
)
f.auto_forecast(call_me="gbt_cv")
```

23.4 Backtest models

- Backtesting is a process in which the final chosen model is re-validated by seeing its average performance on the last x-number of forecast horizons available in the data
- With scalecast, pipeline objects can be built and backtest all applied models to see the best one over several forecast horizons
- See the documentation for more information

[20]:
```
from scalecast.Pipeline import Pipeline
from scalecast.util import backtest_metrics
```

[21]:
```
def forecaster(f):

(continued from previous page)

```
    f" {rmse:.2f}, MAE of {mae:.2f}, and R2 of {r2:.2%} over a full 120-period"
    " forecast window."
)
```

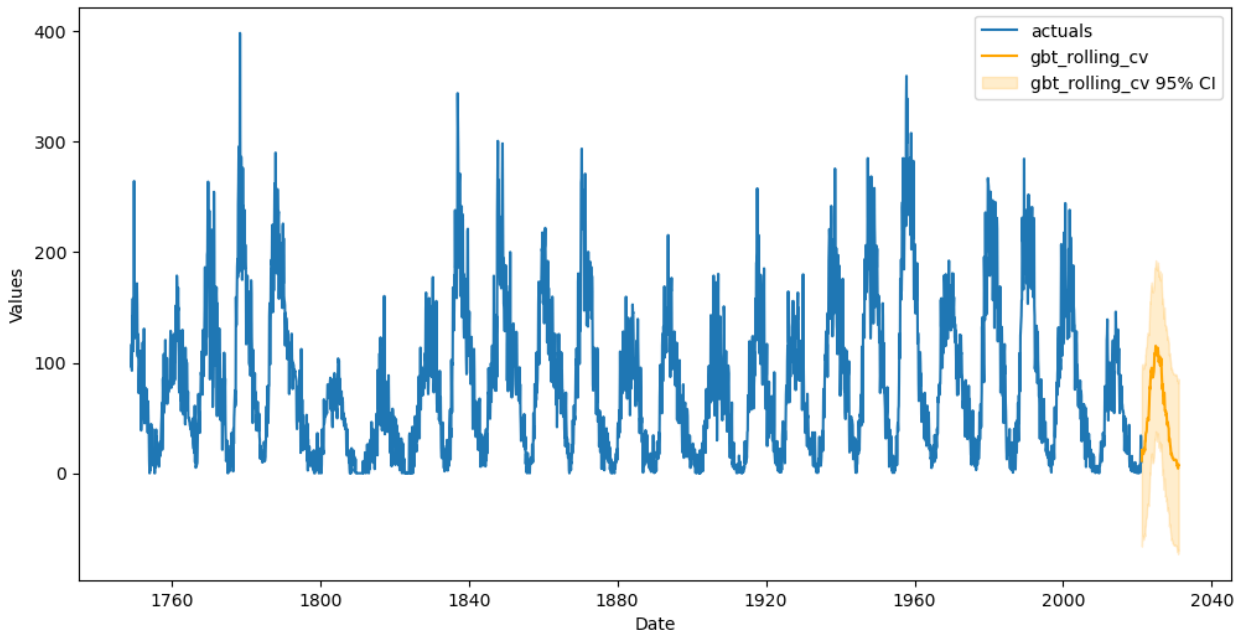
```
The best model, according to the RMSE over 5 backtest iterations was gbt_rolling_cv. On␣
↪average, we can expect this model to have an RMSE of 34.89, MAE of 27.76, and R2 of 70.
↪41% over a full 120-period forecast window.
```

An extension of this analysis could be to choose regressors more carefully (see here) and to use more complex models (see here).

23.5 The Eye Test

In addition to all the objective validation performed in this notebook, one of the most important questions to ask is if the forecast looks reasonable. Does it pass the common sense test? Below, we plot the 120-forecast period horizon from the best model.

[29]:
```
f.plot(models=best_model, ci = True)
plt.show()
```



[ ]:
```

```

CHAPTER

TWENTYFOUR

VECM

- Using a VECM to predict FANG stocks
- See the VECM documentation

[1]:
```
import pandas as pd
import numpy as np
from pandas_datareader import data as pdr
import yfinance as yf
from scalecast.Forecaster import Forecaster
from scalecast.MVForecaster import MVForecaster
from scalecast.Pipeline import Transformer, Reverter, MVPipeline
from scalecast.util import (
    find_optimal_lag_order,
    find_optimal_coint_rank,
    Forecaster_with_missing_vals,
)
from scalecast.auxmodels import vecm
from scalecast.multiseries import export_model_summaries
from scalecast import GridGenerator
import matplotlib.pyplot as plt
```

[2]:

24.2 Augmented Dickey Fuller Tests to Confirm Unit-1 Roots

[5]:
```
for stock, f in zip(FANG,fs):
    adf_result = f.adf_test(full_res=True)
    print('the stock {} is {}stationary at level'.format(
        stock,
        'not ' if adf_result[1] > 0.05 else ''
    )
    )
```

```
the stock META is not stationary at level
the stock AMZN is not stationary at level
the stock NFLX is not stationary at level
the stock GOOG is not stationary at level
```

[6]:
```
for stock, f in zip(FANG,fs):
    adf_result = f.adf_test(diffy=True,full_res=True)
    print('the stock {} is {}stationary at its first difference'.format(
        stock,
        'not ' if adf_result[1] > 0.05 else ''
    )
    )
```

```
the stock META is stationary at its first difference
the stock AMZN is stationary at its first difference
the stock NFLX is stationary at its first difference
the stock GOOG is stationary at its first difference
```

24.3 Measure IC to Find Optimal Lag Order

- this is used to run the cointegration test

[7]:
```
lag_test = find_optimal_lag_order(mvf,train_only=True)
pd.DataFrame(
    {
        'aic':lag_test.aic,
        'bic':lag_test.bic,
        'hqic':lag_test.hqic,
        'fpe':lag_test.fpe,
    },
    index = ['optimal lag order'],
).T
```

[7]:
```
      optimal lag order
aic                  27
bic                   1
hqic                  3
fpe                  27
```

24.4 Johansen cointegration test

[8]:
```
coint_res = find_optimal_coint_rank(
    mvf,
    det_order=1,
    k_ar_diff=10,
    train_only=True,
)
print(coint_res)
coint_res.rank
```

```
Johansen cointegration test using trace test statistic with 5% significance level
=====================================
r_0 r_1 test statistic critical value
-------------------------------------
  0   4          56.60          55.25
  1   4          33.50          35.01
-------------------------------------
```

[8]:
```
1
```

We found a cointegration rank of 1.

24.5 Run VECM

- Now, we can specify a grid that will try more lags, deterministic terms, seasonal fluctuations, and cointegration ranks of 0 and 1

[9]:
```
vecm_grid = dict(
    lags = [0], # required to set this to 0 for the vecm model in scalecast
    freq = ['B'], # only necessary to suppress a warning
    k_ar_diff = range(1,66), # lag orders to try
    coint_rank = [0,1],
    deterministic = ["n","co","lo","li","cili","colo"],
    seasons = [0,5,30,65,260],
)

mvf.set_estimator('vecm')
mvf.ingest_grid(vecm_grid)
mvf.limit_grid_size(100,random_seed=20)
mvf.cross_validate(k=3,verbose=True)
mvf.auto_forecast()

results = mvf.export('model_summaries')
results[[
    'ModelNickname',
    'Series',
    'TestSetRMSE',
    'TestSetMAE',
]]
```

```

```

[36]:
```
results = export_model_summaries(dict(zip(FANG,fs)))
```

24.9 View Results

[37]:
```
model_rmses = results.groupby('ModelNickname')['TestSetRMSE'].mean().sort_values().reset_
↪index()
model_rmses
```

[37]:

	ModelNickname	TestSetRMSE
0	xgboost	27.918698
1	knn	41.832711
2	mlr	42.519262
3	gbt	43.895070
4	elasticnet	44.320649
5	lightgbm	44.554279

The above table is the mean mape performance from each model over all series.

[38]:
```
series_rmses = results.groupby('Series')['TestSetRMSE'].min().reset_index()
series_rmses['Model'] = [
    results.loc[
        results['TestSetRMSE'] == i,
        'ModelNickname'
    ].values[0] for i in series_rmses['TestSetRMSE']
]
series_rmses
```

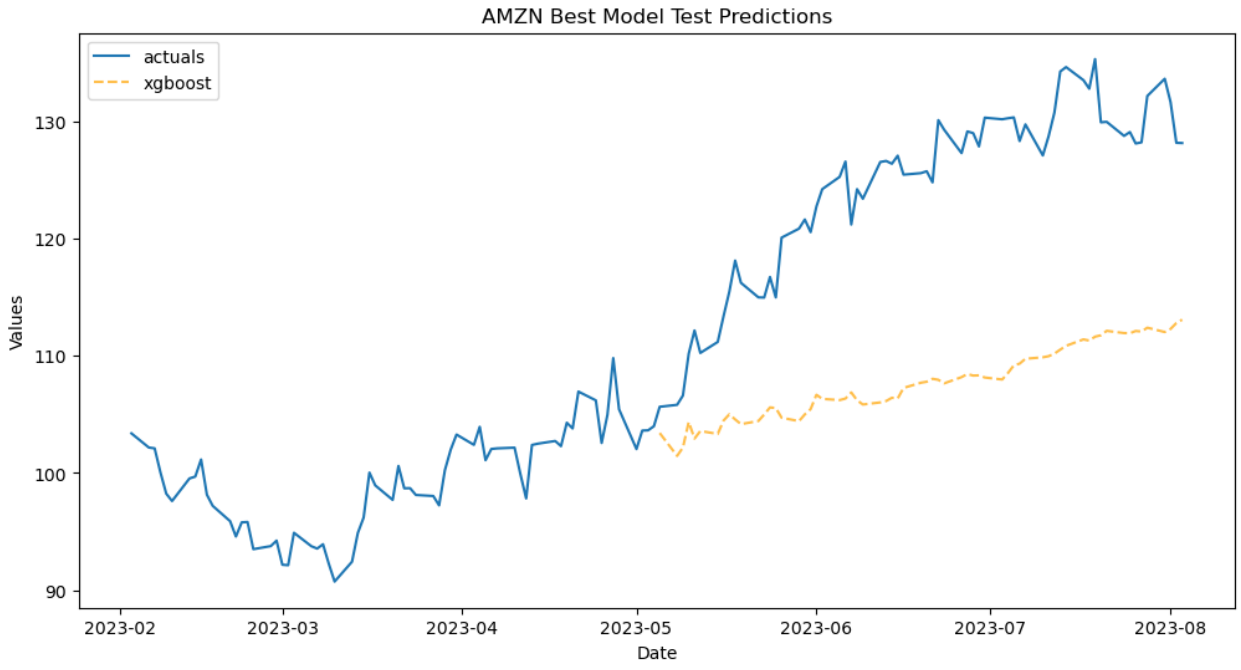
[38]:
```
  Series  TestSetRMSE    Model
0   AMZN    17.433315  xgboost
1   GOOG    12.892690  xgboost
2   META    10.509525  xgboost
3   NFLX    70.839262  xgboost
```

[39]:
```
series_rmses['TestSetRMSE'].mean()
```

[39]:
```
27.918697955026953
```

The above table shows the best model for each series and its derived RMSE. The average RMSE of all these models applied to the individual series is 27.9, but being so dependent on the test set to choose the model probably leads to overfitting.

[41]:
```
fs[1].plot_test_set(
    models='xgboost',
    include_train=130,
)
plt.title('AMZN Best Model Test Predictions')
plt.show()
```



[42]:
```
fs[1].plot(
    models='xgboost',
)
plt.title('AMZN Best Model Forecast')
plt.show()
```
